

MODULI STACKS OF QUIVER BUNDLES WITH APPLICATIONS TO HIGGS BUNDLES

MAHMUD AZAM AND STEVEN RAYAN

ABSTRACT. We provide a general method for constructing moduli stacks whose points are diagrams of vector bundles over a fixed base, indexed by a fixed simplicial set — that is, quiver bundles of a fixed shape. We discuss some constraints on the base for these moduli stacks to be Artin and observe that a large class of interesting schemes satisfy these constraints. Using this construction, we recover Nakajima quiver varieties and provide an alternate construction for moduli stacks of Higgs bundles along with a proof of algebraicity following readily from the algebraicity of moduli stacks of quiver bundles. One feature of our approach is that, for each of the moduli stacks we discuss, there are moduli stacks that are Artin, parametrizing morphisms of the objects being classified. We discuss some potential applications of this in categorifying non-abelian Hodge theory in a sense we will make precise. We also discuss potential applications of our methods and perspectives to the subjects of quiver varieties, abstract moduli theory, and homotopy theory.

1. INTRODUCTION

Solving moduli problems is one of the modern techniques for constructing new and interesting spaces. Moduli spaces tend to be very nice objects from a geometric or topological point of view, but the imposition of a stability condition comes at the cost of obscuring some otherwise useful features — for example, over a Riemann surface or complex curve, the moduli space of Higgs bundles is only birationally equivalent to the cotangent bundle of the moduli space of stable bundles. On the other hand, moduli stacks are more flexible and tend to have more obvious versions of features like the aforementioned one (so that the moduli stack of Higgs bundles is exactly the tangent bundle to the stack of bundles), but depending on how they are defined they may be cumbersome to interact with.

In this article, we wish to define, in a relatively straightforward way, a moduli stack whose points are diagrams, which may or may not commute, of vector bundles over a fixed stack. Such a moduli stack will be called a *moduli stack of quiver bundles*. The homological algebra of quiver bundles was developed in [GK05], and moduli spaces of these objects were considered very explicitly for low-genus curves in [RS18; RS21] using a stability condition induced by viewing these as Higgs bundles of a particular sub-diagonal form, while these were constructed in far greater generality in [Sch05; Sch08; Sch13; Sch17; Sch20; Sch22], just for example. Some of the main motivations, in very general terms, of this programme are:

- (i) to categorify moduli problems involving vector bundles in a suitable sense to be expanded upon — see Section 4 and Remark 4.13;
- (ii) to construct and study a categorified stack of Higgs bundles in this sense;
- (iii) to enlarge some existing connections between quiver bundles and Higgs bundles, building on the relationship where the former, at least in Dynkin type A , appear as fixed points of an algebraic \mathbb{C}^\times -action on the moduli space of the latter (cf. for example [Ray18]);
- (iv) to recover a notion of mapping space for quiver bundles, in particular for vector bundles themselves and Higgs bundles, and examine any connections thereof with homotopy theory;
- (v) to explore some potential connections between abstract moduli theory and homotopy theory;

The main goal of this paper is to initiate some minimal foundation for such investigations. Moduli stacks of quiver bundles have been constructed in great generality in [HP25, Proposition 7.1 and Corollary 7.2] in the context of derived stacks and derived analytic stacks. It was pointed out to us by the authors of that paper after submitting the present work for review. Nevertheless, in this paper, we provide an alternate, perhaps simpler, construction which we can work with in the context of 1-stacks over the fppf site of affine schemes over a ground ring k , without using any derived technology. Hence, proofs in the non-derived setting are perhaps simpler in our approach. At

the same time, some of our results, in the non-derived setting, are slightly more specific — see remarks 1.1 and 6.11.

To accomplish our goals in as “model-agnostic” a way as possible, we set up a minimal context for defining moduli stacks of quiver bundles in Section 2, which we will then specialize and build on to study examples of interest. In doing so, we prioritize a simplicial approach over existing approaches to moduli stacks of, say, Higgs bundles, e.g. [Pan+13, Corollary 2.6(2)]. In Section 3, we construct a moduli stack parametrizing triples (E, F, f) of two vector bundles E, F over a fixed base and a vector bundle map $f : E \rightarrow F$. We use this stack to then construct moduli stacks parametrizing diagrams of vector bundles — that is, quiver bundles — over a fixed base indexed by a fixed simplicial set in Section 4. In this section, we also establish the algebraicity, by which we mean the property of being an Artin stack, of the stacks constructed in the case of a somewhat general base 1-stack over the fppf site of commutative rings and a finite indexing simplicial set. From this, we recover the algebraicity of such stacks when the base is a projective variety over a field.

Remark 1.1. We should clarify here that such algebraicity results are available in far greater generality. For instance, [DPS25, Proposition II.2.8] along with Toën-Vaquié’s representability theorem ([DPS25, Theorem II.2.22] or [TV07, Theorem 3.6]) show that the derived moduli stack of quiver representations in perfect complexes over a smooth variety over a field k is locally geometric and locally of finite presentation. While our algebraicity results can be recovered from this, our constructions and method of proof are different. Furthermore, our methods apply directly in the non-derived setting and yield additional properties of the constructed moduli stacks under suitable hypotheses on the base stack — see Theorem 4.10 and Remark 4.12.

In Section 5, we sketch how to recover quiver varieties and Nakajima quiver varieties from our framework, the precise details of which we leave for future work. In Section 6, we provide a construction of a moduli stack of Higgs bundles, under the conjecture that the moduli stacks of vector bundles and triples admit suitable morphisms of stacks sending vector bundles and their maps to the respective tensor products. We observe that the algebraicity of this moduli stack of Higgs bundles is immediate from the moduli stacks of quiver bundles. Here, we also speculate about a version of non-Abelian Hodge theory involving a stack parametrizing morphisms of Higgs bundles. In Section 7, we discuss some potential links between moduli theory and homotopy theory inspired by the perspectives in this work.

Conventions. We will follow the notation and conventions of [Lur09; Lur17; Lur18] for the most part. In particular, by infinity category we will mean quasicategory and by a space or animus, we will mean a Kan complex. \mathbf{CRing} will stand for E_∞ -algebras in the quasicategory of spectra. $\mathbf{CRing}^\heartsuit$ will stand for the category of commutative rings which is also the heart of

\mathbf{CRing} . \mathbf{CRing}^Δ will stand for animated rings. A difference here will be that we will use \mathbf{sSet} to denote the quasicategory of simplicial sets. We will use $pr_i : \prod_{k=1}^n X_k \rightarrow X_i$ to denote projections of products and $\pi_i : \lim_k X_k \rightarrow X_i$ to denote projections or structure maps of limits. We will use $\Delta : X \rightarrow X \times X$ to denote diagonal maps. A potential source of confusion will be our use of Δ to also denote the simplicial indexing category but hopefully, this confusion will be easily dispelled by context. For a quasicategory \mathcal{C} , we will write $\mathrm{Hom}_{\mathcal{C}}(A, B)$ for the Kan complex of maps $A \rightarrow B$ and $\mathcal{H}\mathrm{om}_{\mathcal{C}}(A, B)$ for internal Hom 's. We will use the term “algebraic stack” to denote Artin 1-stacks over the fppf site of affine schemes over a base ring.

Given a category \mathcal{C} and a space or animus I , we will write \underline{I} for the constant presheaf $\mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}$ with value I — that is, the presheaf $c \mapsto I, \forall c \in \mathcal{C}$. Whenever we mention limits or colimits, we mean limits in the respective quasicategories — for instance, in the case of nerves of 1-categories, these will be usual limits and colimits; for $(2, 1)$ -categories such as those of 1-stacks, we will mean strong 2-limits and 2-colimits (that is, $(2, 1)$ -limits and -colimits); and for quasicategories, we will mean the fully ∞ -categorical limits and colimits such as those of sheaves of spaces over an ∞ -categorical site or ∞ -stacks. Another potential source of confusion is the word “pullback” which could mean (pre)sheaf pullbacks or fibre products. However, it will be clear from context which we mean.

Finally, we will make use of the language of internal categories or category objects in $(2, 1)$ -categories — mainly in the $(2, 1)$ -category of 1-stacks over some site of affine schemes. That is, we will consider some ambient 2-category \mathcal{D} and an object in \mathcal{D} of “objects” \mathcal{C}_0 and an object in \mathcal{D} of “morphisms” \mathcal{C}_1 , equipped with maps $s, t : \mathcal{C}_1 \rightarrow \mathcal{C}_0$ to be thought of as sending morphisms to their sources and targets, a map $e : \mathcal{C}_0 \rightarrow \mathcal{C}_1$ to be thought of as sending an object to its identity morphism, and a morphism $c : \mathcal{C}_1 \times_{\mathcal{C}_0} \mathcal{C}_1 \rightarrow \mathcal{C}_1$, where the pullback is of the diagram $\mathcal{C}_1 \xrightarrow{s} \mathcal{C}_0 \xleftarrow{t} \mathcal{C}_1$, to be thought of as sending a composable pair of morphisms to their composite. These maps satisfy diagrams that express the associativity and unitality of composition. Of course, these are diagrams in a $(2, 1)$ -category.

Acknowledgements. The authors thank Kuntal Banerjee, Daniel Halpern-Leistner, Matthew Koban, Kobi Kremnizer, Carlos Simpson, Motohico Mulase, and Qixiang Wang for very useful discussions. We acknowledge Dat Minh Ha for valuable discussions around the formulation of Theorem 4.10. The authors are especially grateful to Toni Annala for hosting the first-named author for a crucial research stay at the Institute for Advanced Study in March 2024 and for many discussions after that time, leading to a number of crucial developments around the parametrization of vector bundle triples in this work. We are also indebted to Antoine Bourget for hosting the first-named author for a two-month research stay during the months of October and November 2024 at CEA Saclay, during which the major part of the

section on quiver varieties was completed, and for many discussions about quiver varieties. We are pleased to acknowledge that this stay was funded by a High Level Scientific Fellowship (HLSF) for graduate students from Campus France and the Embassy of France in Canada. We are grateful to Mauro Porta and Francesco Sala for pointing us to their work generalizing some of our results to the setting of derived geometry. Formative moments towards the completion of the work occurred during the Arithmetic Quantum Field Theory Conference at Harvard in March 2024, in which the first-named author participated through a generous conference fellowship from the Arithmetic Quantum Field Theory Program; the Workshop on Advances in Higgs Bundles at the Brin Mathematics Research Centre in Maryland in April 2024 in which the second-named author was a speaker and participant; the 2nd Simons Math Summer Workshop, convened around the topic of “Moduli” at the Simons Center for Geometry and Physics in July 2024, in which the first-named author was a participant in residence, once again with generous student funding; and finally the Workshop on Hamiltonian Geometry and Quantization at the Fields Institute in July 2024, in which the second-named author was a speaker and participant. The authors thank the various organizing teams of these gatherings for creating such stimulating research environments. The second-named author was supported during the development of this work by a Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant, a Canadian Tri-Agency New Frontiers in Research Fund (NFRF) Exploration Stream Grant, and a Pacific Institute for the Mathematical Sciences (PIMS) Collaborative Research Group Award, for which this manuscript is PIMS report PIMS-20240716-CRG34. The first-named author was funded by a University Saskatchewan Dean’s Scholarship, an NSERC Canada Graduate Scholarship (Doctoral), and the second-named author’s Discovery Grant. We gratefully acknowledge these funding sources.

2. CONTEXT

Let \mathcal{C} be a quasicategory to be thought of as the quasicategory of local models for a geometric theory — for instance, affine k -schemes $\mathcal{C} = \mathrm{CRing}_{/k}^{\heartsuit, \mathrm{op}}$, or spectral affine schemes $\mathcal{C} = \mathrm{CRing}_{/k}^{\mathrm{op}}$, or derived affine schemes $\mathcal{C} = \mathrm{CRing}_{/k}^{\Delta, \mathrm{op}}$. We assume \mathcal{C} is complete and cocomplete. In particular, it has fibre products, or dually, tensor products of commutative algebras. Let τ be a subcanonical topology on \mathcal{C} . Consider sheaves of spaces or anima on \mathcal{C} with respect to τ and denote the quasicategory of these objects $\mathrm{St}_{\mathcal{C}, \tau}$, omitting τ from notation when there is no confusion — these are to be thought of as stacks, spectral stacks or derived stacks. Notice that we do not yet concern ourselves with any kind of algebraicity. We also adopt a notational convention for convenience: we will write $\mathrm{St}_{\mathcal{C}}^n$ for the full subcategory of n -truncated objects — that is, sheaves of $(n, 1)$ -groupoids on \mathcal{C} . We will take $n = \infty$ to mean $\mathrm{St}_{\mathcal{C}}^{\infty} = \mathrm{St}_{\mathcal{C}}$. We will mostly be concerned

with $n = 1$ in this paper, but will make our definitions and constructions for $n = \infty$ whenever possible, as we intend to eventually extend our work in this paper to most available models of geometry including derived algebraic geometry, spectral algebraic geometry, and derived analytic geometry with modifications as necessary.

We will then consider some assumptions on $\mathrm{St}_{\mathcal{C}}^n$ for all n , modeled on the properties of the categories of quasicoherent sheaves and vector bundles over 1-stacks in (non-derived) algebraic geometry — that is, objects of $\mathrm{St}_{\mathrm{CRing}/k}^1, \heartsuit, \mathrm{op}, \mathrm{fppf}$.

Assumption 2.1. For each $X \in \mathrm{St}_{\mathcal{C}}^n$, there exists a symmetric monoidal stable quasicategory $\mathrm{QCoh}(X)$ equipped with a t -structure and admitting small colimits. We further assume that $\mathrm{QCoh}(X)$ is symmetric monoidal with the product preserving colimits in each variable — that is, the monoidal product is bilinear. We will always assume a choice of unit object for the monoidal product and denote it \mathcal{O}_X . As the notation suggests, $\mathrm{QCoh}(X)$ is to be thought of as the quasicategory of chain complexes of quasicoherent sheaves on X — this has a bilinear monoidal product by [Lur18, Proposition 2.1.0.3, Proposition 2.2.4.1, Proposition 2.2.4.2].

Assumption 2.2. $\mathrm{QCoh}(X)$ has a full subcategory $\mathrm{Vect}(X)$ closed under the monoidal product and containing the unit of the monoidal product, and hence inheriting a symmetric monoidal structure from $\mathrm{QCoh}(X)$. Of course, $\mathrm{Vect}(X)$ is to be thought of as the full subcategory of finite locally free sheaves.

Notation 2.3. In the case that $\mathcal{C} = \mathrm{CRing}_{/R}^{\heartsuit, \mathrm{op}}$, $n = 1$ for some ring R , we will also write $\mathrm{QCoh}(X)$ and $\mathrm{Vect}(X)$ to denote the hearts of the respective categories — that is, the usual categories of quasicoherent sheaves or finite locally free sheaves respectively.

Assumption 2.4. $\mathrm{Vect}(X)$ is closed under coproducts in $\mathrm{QCoh}(X)$, and these coproducts coincide with products in $\mathrm{Vect}(X)$. We will denote the product/coproduct by $- \oplus -$.

Assumption 2.5. There is a functor $(-)^{\vee} : \mathrm{Vect}(X) \rightarrow \mathrm{Vect}(X)$ such that $E^{\vee} \otimes F \simeq \mathcal{H}om_{\mathrm{Vect}(X)}(E, F)$, the internal Hom, for each $E, F \in \mathrm{Vect}(X)$ and we have a closed monoidal structure on $\mathrm{Vect}(X)$ given by the adjunction $- \otimes E \dashv E^{\vee} \otimes - \simeq \mathcal{H}om_{\mathrm{Vect}(X)}(E, -)$.

Assumption 2.6. The assignment QCoh extends to a sheaf of quasicategories:

$$\begin{array}{lll} \mathrm{QCoh} & : & \mathcal{C}^{\mathrm{op}} \longrightarrow \mathcal{C}at_{\infty} \\ & : & Y \longmapsto \mathrm{QCoh}(Y) \\ & : & (f : Y \longrightarrow Z) \longmapsto (f^* : \mathrm{QCoh}(Z) \longrightarrow \mathrm{QCoh}(Y)) \end{array}$$

which restricts to a sheaf of categories:

$$\begin{array}{ccccc} \mathbf{Vect} & : & \mathcal{C}^{\mathrm{op}} & \longrightarrow & \mathbf{Cat}_{\infty} \\ & : & Y & \longmapsto & \mathbf{Vect}(Y) \\ & : & (f : Y \longrightarrow Z) & \longmapsto & (f^* : \mathbf{Vect}(Z) \longrightarrow \mathbf{Vect}(Y)) \end{array}$$

We will write \mathbf{QCoh} and \mathbf{Vect} to also denote the left Kan extensions of the above functors along the Yoneda embedding $\mathcal{C} \hookrightarrow \mathbf{St}_{\mathcal{C}}^n$.

Assumption 2.7. For any $f : X \longrightarrow Y$, the pullback functor f^* is symmetric monoidal and preserves duality: $f^*(E^{\vee}) \simeq (f^*E)^{\vee}$ for each $E \in \mathbf{Vect}(X)$.

Assumption 2.8. For each $F \in \mathbf{Vect}(X)$, there is a map $\mathrm{tr} : F \otimes F^{\vee} \longrightarrow \mathcal{O}_X$ such that for each $E, G \in \mathbf{Vect}(X)$, the map

$$\mathrm{id} \otimes \mathrm{tr} \otimes \mathrm{id} : E^{\vee} \otimes F \otimes F^{\vee} \otimes G \longrightarrow E^{\vee} \otimes \mathcal{O}_X \otimes G \simeq E^{\vee} \otimes G$$

is the internal composition map of $\mathbf{Vect}(X)$ for its closed monoidal structure.

Assumption 2.9. There exists a functor $\mathcal{V}_X : \mathbf{QCoh}(X) \longrightarrow \mathbf{St}_{\mathcal{C}/X}^n$ such that $\mathbf{Vect}(X) \hookrightarrow \mathbf{QCoh}(X) \xrightarrow{\mathcal{V}_X} \mathbf{St}_{\mathcal{C}/X}^n$ is faithful. In addition, the functor \mathcal{V}_X restricted to $\mathbf{Vect}(X)$ is functorial in X , in the sense that for every morphism $f : X \longrightarrow Y$, the functor $f^* : \mathbf{Vect}(Y) \longrightarrow \mathbf{Vect}(X)$ makes the following diagram of quasicategories commute:

$$\begin{array}{ccc} \mathbf{Vect}(Y) & \xrightarrow{f^*} & \mathbf{Vect}(X) \\ \mathcal{V}_Y \downarrow & & \downarrow \mathcal{V}_X \\ \mathbf{St}_{\mathcal{C}/Y}^n & \xrightarrow{f^*} & \mathbf{St}_{\mathcal{C}/X}^n \end{array}$$

where the bottom horizontal arrow is given by taking pullbacks along f . This is to be thought of as sending a quasicoherent sheaf to the relative spectrum of the symmetric algebra of its dual. For any $Y, Z \in \mathbf{St}_{\mathcal{C}/X}^n$ with $Y \simeq \mathcal{V}_X(E), Z \simeq \mathcal{V}_X(F)$ for $E, F \in \mathbf{Vect}(X)$, we will define $Y \otimes Z := \mathcal{V}_X(E \otimes F), Y^{\vee} := \mathcal{V}_X(E^{\vee})$. The definition and basic properties of the relative spectrum construction for 1-stacks can be found in [LM00, Chapter 14, §14.2].

Definition 2.10. We define $\mathcal{M}_{\mathbf{Vect}(X)}$ as the mapping stack $\mathrm{Map}(X, \mathbf{Vect})$ so that maps $f : U \longrightarrow \mathcal{M}_{\mathbf{Vect}(X)}$ are maps $U \times X \longrightarrow \mathbf{Vect}$ and hence correspond to objects of the unstraightening of \mathbf{Vect} over $U \times X$.

Assumption 2.11. For each $X \in \mathbf{St}_{\mathcal{C}}^n$, there exists a map $p_X : \mathcal{E}_X \longrightarrow \mathcal{M}_{\mathbf{Vect}(X)} \times X$, such that for every $U \in \mathbf{St}_{\mathcal{C}}^n$ and every $E \in \mathbf{Vect}(U \times X)$, there exists a unique-up-to-equivalence map $f_E : U \longrightarrow \mathcal{M}_{\mathbf{Vect}(X)}$ and an equivalence:

$$(f_E \times \mathrm{id}_X)^* \mathcal{E}_X \simeq \mathcal{V}_X(E)$$

This is to be thought of as $\mathcal{M}_{\mathbf{Vect}(X)}$ being a fine moduli stack of vector bundles over X with a universal vector bundle \mathcal{E}_X . We will call them as such.

Remark 2.12. In the concrete geometric contexts, this makes $\mathcal{M}_{\text{Vect}(X)}$ the moduli stack of vector bundles over X . In particular, for $\text{St}_{\text{CRing}_{/k}^{\heartsuit, \text{op}}}^1$, $\mathcal{M}_{\text{Vect}(X)}$ is precisely the moduli stack of vector bundles over X (as defined in, for example, [CW17, First paragraph of §7.3]). To see this, it suffices to unwrap the definition of the Grothendieck construction of Vect . A similar argument shows that it coincides with the moduli stack of vector bundles in the derived setting, as defined in, for example [AI22, §3].

Notation 2.13. For brevity, we will often write B_X to denote the stack $\mathcal{M}_{\text{Vect}(X)} \times X$.

Convention 2.14. In the case that $\mathcal{C} = \text{CRing}^{\heartsuit, \text{op}}, n = 1$, we will take \mathcal{E}_X to mean the universal vector bundle on $\mathcal{M}_{\text{Vect}(X)} \times X$, which is finite locally free, but has a different rank on each connected component of B_X .

Theorem 2.15. *The $(2, 1)$ -category $\text{St}_{\text{CRing}^{\heartsuit, \text{op}}, \text{fppf}}^1$ of 1-stacks on the site of commutative rings with the fppf topology satisfies the above assumptions.*

Proof. Omitted, as these are well known properties. \square

This is the case we will be most interested in for the present work.

Remark 2.16. We should clarify that these assumptions are satisfied by all 1-stacks irrespective of any form of algebraicity (Artin, Deligne-Mumford, etc.) or other special properties.

Remark 2.17. For $n = \infty$, if we take \mathcal{C} to be the opposite of animated commutative rings, $\text{St}_{\mathcal{C}}$ to be derived stacks, QCoh and Vect to be the functors sending derived stacks to the quasicategories of complexes of the respective objects, and $\mathcal{V}_X := \underline{\text{Spec}}_X \text{LSym}^*(-)$, then these assumptions should be satisfied (again, regardless of algebraicity/geometricity). We wish to explore the applicability of the techniques of this paper in the derived setting in future work. It is possible that this will yield slightly more specific results, even in the derived setting, than the ones available in the literature (see Remark 1.1 and Remark 6.11).

Remark 2.18. For spectral algebraic geometry, one needs exercise caution, for the relative spectrum of the symmetric algebra of a locally free sheaf might not be flat.

Remark 2.19. Since the various moduli spaces related by non-Abelian Hodge theory have analytic forms, and the complex non-Abelian Hodge correspondence is heavily dependent on PDE theory, it might be worthwhile to explore the applicability of the techniques of this paper in the context of analytic stacks. Since the above assumptions hold for the $(2, 1)$ -category of stacks with no additional constraints like algebraicity, by formal/categorical reasons, we expect them to hold for the analytic stacks of [CS19] and [BKK24] as well, for similar reasons, as these are just stacks over sites of analytic and simplicial commutative complete bornological rings respectively.

Given any setting of geometry where the above assumptions are satisfied, we will make the following basic definitions in that setting:

Definition 2.20 (Quiver). We will use the term quiver for a simplicial set I for keeping connection with the theory of quiver varieties. If I is a standard simplex Δ^n , we will call quivers of shape I , standard n -quivers.

Remark 2.21. We discuss the connection of the present work with ordinary and Nakajima quiver varieties in Section 5.

Example 2.22. The following is a drawing of quiver in our context:

$$\begin{array}{ccc} a & \longrightarrow & b \\ \downarrow & \searrow & \downarrow \\ c & \longrightarrow & d \end{array} \quad \begin{array}{c} \times \end{array}$$

where the “ \times ” indicates that we do not have a 2-simplex witnessing the commutativity of the bottom left triangle. That is, quivers in this paper may or may not have composites of composeable arrows. In usual quiver theory, existence of composites is never assumed.

Remark 2.23. Labels on vertices of a quiver are used to construct the space of representations as a finite dimensional vector space which is then used to construct quiver varieties. In our case, the space of representations is replaced by a moduli stack $\mathcal{M}_{\text{Vect}(X), I}$ parametrizing diagrams of vector bundles of shape I for a quiver I . Taking X to be the point gives a moduli stack of representations in vector spaces, but of all possible dimensions. Then, if a labeling is given for I , we can consider the full substack of $\mathcal{M}_{\text{Vect}(X), I}$ consisting of those diagrams whose vertices have ranks/dimensions corresponding to the labels. It is likely that these substacks have similar properties to the original moduli stack and under a suitable notion of GIT for stacks (for example, [AHH23]), they recover classical quiver varieties — see Section 5. However, the main results of this paper are not concerned with such substacks or quiver varieties and we will avoid discussing labels any further.

Definition 2.24 (Quiver Bundle). A quiver bundle over $X \in \text{St}_{\mathcal{C}}^n$ is just a map of simplicial sets $f : I \longrightarrow \text{Vect}(X)$. If I is a standard n -quiver, then f is called a standard n -quiver bundle.

Convention 2.25. Unless specified otherwise, in all discussions involving quiver bundles we will always assume a fixed stack $X \in \text{St}_{\mathcal{C}}$ over which we consider quiver bundles.

3. MODULI STACK OF VECTOR BUNDLE MORPHISMS

As a foundation, we first define a stack whose points are triples consisting of two vector bundles and a morphism between them. Let $X \in \text{St}_{\mathcal{C}}$ be a stack over \mathcal{C} , $U \in \mathcal{C}$, and E, F , two vector bundles on $U \times X$. For

notational convenience, we will write $B_X := \mathcal{M}_{\text{Vect}(X)} \times X$ so that we have the universal vector bundle $p_X : \mathcal{E}_X \rightarrow B_X$, where we are identifying \mathcal{E}_X with $\mathcal{V}_X(\mathcal{E}_X)$. We obtain two maps $u_E, u_F : U \rightarrow \mathcal{M}_{\text{Vect}(X)}$ such that $E \simeq (u_E \times \text{id}_X)^* \mathcal{E}_X, F \simeq (u_F \times \text{id}_X)^* \mathcal{E}_X$, by the universal property of $\mathcal{M}_{\text{Vect}(X)}$, the moduli stack of vector bundles on X . We will write $B_X \xleftarrow{pr_1} B_X \times B_X \xrightarrow{pr_2} B_X$ for the two projections. We recall our assumption that $(pr_i^* \mathcal{E}_X)^\vee \simeq pr_i^* (\mathcal{E}_X^\vee)$ which allows us to write $pr_i^* \mathcal{E}_X^\vee$ without confusion. We then consider the vector bundle

$$p : \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X = pr_1^* \mathcal{E}_X^\vee \otimes_{\mathcal{O}_{B_X \times B_X}} pr_2^* \mathcal{E}_X \rightarrow B_X \times B_X$$

Then, a morphism of vector bundles $E \rightarrow F$ corresponds to a global section of the bundle $E^\vee \otimes F$. This bundle, however, is isomorphic to the pullback $(u_E \times \text{id}_X, u_F \times \text{id}_X)^* (\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$, so that the following square is Cartesian:

$$\begin{array}{ccc} E^\vee \otimes F & \xrightarrow{\quad} & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ \downarrow & \lrcorner & \downarrow \\ U \times X & \xrightarrow{(u_E \times \text{id}_X, u_F \times \text{id}_X)} & B_X \times B_X \end{array}$$

Hence, such a global section corresponds, in turn, to a morphism of $f : U \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ such that $pf \simeq (u_E \times \text{id}_X, u_F \times \text{id}_X)$. On the other hand, we get four maps $u_1, u_3 : U \times X \rightarrow \mathcal{M}_{\text{Vect}(X)}, u_2, u_4 : U \times X \rightarrow X$, by composing ps with the projections onto the different factors of $\mathcal{M}_{\text{Vect}(X)}$ and X . Then, $pf = (u_1, u_2, u_3, u_4)$. That is, a vector bundle morphism $E \rightarrow F$ corresponds to a morphism of stacks $f : U \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ and an equivalence

$$(1) \quad (pr_1 pf, pr_2 pf, pr_3 pf, pr_4 pf) \simeq (u_E \times \text{id}_X, u_F \times \text{id}_X)$$

In turn, this is equivalent to a commutative diagram of stacks:

$$(2) \quad \begin{array}{ccccc} U & \xrightarrow{(u_E, u_F)} & \mathcal{M}_{\text{Vect}(X)} \times \mathcal{M}_{\text{Vect}(X)} & & \\ \uparrow pr_1 & & \uparrow (pr_1, pr_3) & & \\ U \times X & \xrightarrow{f} \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \xrightarrow{p} & \mathcal{M}_{\text{Vect}(X)} \times X \times \mathcal{M}_{\text{Vect}(X)} \times X & & \\ \downarrow pr_2 & & \downarrow (pr_2, pr_4) & & \\ X & \xrightarrow{\Delta_X} & X \times X & & \end{array}$$

where Δ_X is the diagonal morphism of X and the vertical maps are the respective projections. A map f as above is a U -point of $\text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$ satisfying the condition specified by the commutativity of 2.

If we translate the condition to the relevant mapping stacks, the commutativity of the top rectangle is equivalent to the commutativity of:

$$\begin{array}{ccc}
 U & \xrightarrow{\bar{f}} & \text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \\
 \downarrow & & \downarrow p \circ - \\
 & & \text{Map}(X, B_X^2) \\
 & & \downarrow \\
 \text{Map}(\text{pt}, \mathcal{M}_{\text{Vect}(X)}^2) & \xrightarrow{!_X} & \text{Map}(X, \mathcal{M}_{\text{Vect}(X)}^2)
 \end{array}$$

where \bar{f} is the unique map corresponding to f , the bottom map is the one induced by the unique morphism of stacks $X \rightarrow \text{pt}$, the top right vertical map is given by post-composition with the vector bundle projection p , and the bottom right vertical map is given by post-composition with the the projection $B_X^2 \rightarrow \mathcal{M}_{\text{Vect}(X)}^2$. Similarly, the commutativity of the bottom rectangle in 2 is equivalent to the commutativity of:

$$\begin{array}{ccc}
 U & \xrightarrow{\bar{f}} & \text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \\
 \downarrow & & \downarrow p \circ - \\
 & & \text{Map}(X, B_X^2) \\
 & & \downarrow \\
 \text{pt} & \xrightarrow{\bar{\Delta}_X} & \text{Map}(X, X^2)
 \end{array}$$

where the bottom map is the unique one corresponding to the diagonal morphism of X , and the bottom right vertical map is the one induced by the projection $B_X^2 \rightarrow X^2$. This leads to the following definition:

Definition 3.1 (Moduli Stack of Triples/Vector Bundle Morphisms). We define the stack $\mathcal{M}_{\text{Vect}(X),1}$ as the following pullback of stacks:

$$\begin{array}{ccc}
 \mathcal{M}_{\text{Vect}(X),1} & \xrightarrow{\quad} & \text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \\
 \downarrow & \lrcorner & \downarrow p \circ - \\
 \mathcal{M}_{\text{Vect}(X)}^2 & & \text{Map}(X, B_X^2) \\
 \simeq \downarrow & & \downarrow \simeq \\
 \text{Map}(\text{pt}, \mathcal{M}_{\text{Vect}(X)}^2) \times \text{pt} & \xrightarrow{!_X \times \bar{\Delta}_X} & \text{Map}(X, \mathcal{M}_{\text{Vect}(X)}^2) \times \text{Map}(X, X^2)
 \end{array}$$

We will call $\mathcal{M}_{\text{Vect}(X),1}$ the moduli stack of triples or the moduli stack of vector bundle morphisms.

We have the following statement, by construction:

Lemma 3.2. *When $\mathcal{C} = \mathbf{CRing}^{\heartsuit, \text{op}}$ and we consider all the above constructions for 1-stacks — that is, in $\mathbf{St}_{\mathcal{C}}^1$ — U -points of $\mathcal{M}_{\mathbf{Vect}(X),1}$ correspond to triples (E, F, f) , where E, F are vector bundles over $U \times X$ and f is a map of vector bundles $E \rightarrow F$.*

The stacks $\mathcal{M}_{\mathbf{Vect}(X)}, \mathcal{M}_{\mathbf{Vect}(X),1}$ can be equipped with the structure of a category object internal to stacks, where the former is the stack of objects and the latter, the stack of morphisms. First, we can define the source and target maps by the following composites:

$$\begin{array}{ll} \mathcal{M}_{\mathbf{Vect}(X),1} & \\ \rightarrow \mathcal{M}_{\mathbf{Vect}(X)} \times \mathcal{M}_{\mathbf{Vect}(X)} & \text{projection of pullback} \\ \xrightarrow{\pi_i} \mathcal{M}_{\mathbf{Vect}(X)} & \text{projection of product} \end{array}$$

The two choices of projection $\mathcal{M}_{\mathbf{Vect}(X)} \times \mathcal{M}_{\mathbf{Vect}(X)} \xrightarrow{\pi_i} \mathcal{M}_{\mathbf{Vect}(X)}, i = 1, 2$ above give two different maps

$$s, t : \mathcal{M}_{\mathbf{Vect}(X),1} \rightarrow \mathcal{M}_{\mathbf{Vect}(X)}$$

If $u : U \rightarrow \mathcal{M}_{\mathbf{Vect}(X),1}$ is a U -point of $\mathcal{M}_{\mathbf{Vect}(X),1}$, then $s \circ u, t \circ u : U \rightarrow \mathcal{M}_{\mathbf{Vect}(X)}$ are the maps corresponding to the source and target of the morphism of vector bundles over $U \times X$ corresponding to u . To see this, we first observe that the following diagram commutes — here, id_X is the map $\text{pt} \rightarrow \text{Map}(X, X)$ corresponding to id_X :

$$\begin{array}{ccccc} U & \xrightarrow{u} & \mathcal{M}_{\mathbf{Vect}(X),1} & \xrightarrow{\quad} & \text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \\ & \searrow & \downarrow & \lrcorner & \downarrow p \circ - \\ & & \text{Map}(\text{pt}, \mathcal{M}_{\mathbf{Vect}(X)}^2) \times \text{pt} & \xrightarrow{!_X \times \overline{\Delta}_X} & \text{Map}(X, \mathcal{M}_{\mathbf{Vect}(X)}^2) \times \text{Map}(X, X^2) \\ & \text{sou} \swarrow & \downarrow (pr_1 \circ -) \times \text{id} & & \downarrow (pr_1 \circ -) \times (pr_1 \circ -) \\ & & \text{Map}(\text{pt}, \mathcal{M}_{\mathbf{Vect}(X)}) \times \text{pt} & \xrightarrow{!_X \times \text{id}_X} & \text{Map}(X, \mathcal{M}_{\mathbf{Vect}(X)}) \times \text{Map}(X, X) \\ & & \downarrow \simeq & & \downarrow \simeq \\ & & \mathcal{M}_{\mathbf{Vect}(X)} & \xrightarrow{\quad} & \text{Map}(X, \mathcal{M}_{\mathbf{Vect}(X)} \times X) \end{array}$$

Let u' denote the map $U \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ given by u . Then, the commutativity of the above diagram implies the commutativity of the following diagram by the Cartesian closed structure of stacks:

$$\begin{array}{ccccc} & & U \times X & & \\ & \swarrow u' & & \searrow (sou) \times \text{id}_X & \\ \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X & \xrightarrow{p} & B_X^2 & \xrightarrow{pr_1} & B_X = \mathcal{M}_{\mathbf{Vect}(X)} \times X \end{array}$$

This shows that $so u$ corresponds to the source of the vector bundle morphism over $U \times X$ given by u . For $t \circ u$, we take pr_2 in place of pr_1 in the above.

It is then natural to seek a morphism $e : \mathcal{M}_{\text{Vect}(X)} \rightarrow \mathcal{M}_{\text{Vect}(X),1}$ that sends a point of $\mathcal{M}_{\text{Vect}(X)}$ to the identity morphism of the vector bundle classified by that point. A map of the form e is equivalent to a map $e' : \mathcal{M}_{\text{Vect}(X)} \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ satisfying the commutativity constraint 2 with U replaced by $\mathcal{M}_{\text{Vect}(X)}$. Given any map $u : U \rightarrow \mathcal{M}_{\text{Vect}(X)}$ corresponding to a vector bundle $E \rightarrow U \times X$, we have the following pasting of Cartesian squares:

$$\begin{array}{ccccc} E^\vee \otimes E & \longrightarrow & \mathcal{E}_X^\vee \otimes \mathcal{E}_X & \longrightarrow & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ \downarrow & \lrcorner & \downarrow & \lrcorner & \downarrow \\ U \times X & \xrightarrow{u \times \text{id}_X} & \mathcal{M}_{\text{Vect}(X)} \times X = B_X & \xrightarrow{\Delta_{B_X}} & B_X \times B_X \end{array}$$

Hence, $e' \circ u$ gives a section of $E^\vee \otimes E$. We have a section $e'' : \mathcal{M}_{\text{Vect}(X)} \times X \rightarrow \mathcal{E}_X^\vee \otimes \mathcal{E}_X$ corresponding to the identity morphism $\mathcal{E}_X \rightarrow \mathcal{E}_X$. This gives a candidate for e' by composing e'' with the canonical map $\mathcal{E}_X^\vee \otimes \mathcal{E}_X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$. Thus, $e' \circ u$ corresponds to the section of $E^\vee \otimes E$ given by the identity morphism $E \rightarrow E$. In turn, $e \circ u$ corresponds to the triple (E, E, id_E) .

Next, it is natural to seek a “composition” map

$$c : \mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \rightarrow \mathcal{M}_{\text{Vect}(X),1}$$

where the pullback is taken for the two maps s, t , such that c sends a point of its domain to the composite of the two triples classified by the two projections of that point to the two copies of $\mathcal{M}_{\text{Vect}(X),1}$. We take inspiration from the case of vector spaces. For three vector spaces U, V, W over a field k , the composition map $\text{Hom}(V, W) \otimes \text{Hom}(U, V) \rightarrow \text{Hom}(U, W)$ is given by the composite:

$$V^* \otimes W \otimes U^* \otimes V \xrightarrow{\cong} V^* \otimes V \otimes U \otimes W \xrightarrow{\text{tr} \otimes \text{id}} k \otimes U^* \otimes W \xrightarrow{\cong} U^* \otimes W$$

where tr is the trace map given by the counit of the Hom-tensor adjunction. We notice that we do have the counit $E^\vee \otimes E \rightarrow \mathcal{O}_Y$ for any vector bundle E over a stack Y , by the Hom-tensor adjunction in $\text{Vect}(X)$. Thus, if we can map $\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1}$ to $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \boxtimes \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$, we can take a trace for two of the factors, but some care must be taken to make sure such a trace exists, since the box tensor product is a tensor product between two different bundles.

To this end, we consider the two projections of the pullback

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \xrightarrow{\pi_i} \mathcal{M}_{\text{Vect}(X),1}, i = 1, 2$$

Each copy of $\mathcal{M}_{\text{Vect}(X),1}$ has the canonical map to $\text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$. This gives two maps:

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \xrightarrow{\pi_i} \mathcal{M}_{\text{Vect}(X),1} \rightarrow \text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

Each of these maps, in turn, correspond to two maps

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \xrightarrow{\pi_i \times \text{id}_X} \mathcal{M}_{\text{Vect}(X),1} \times X \longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$$

for $i = 1, 2$. By chasing U -points for arbitrary U , it is straightforward to verify that these maps make the following diagram commute, where we write \mathcal{M}_1 and \mathcal{M}_0 for $\mathcal{M}_{\text{Vect}(X),1}$ and $\mathcal{M}_{\text{Vect}(X)}$ respectively for brevity:

$$(3) \quad \begin{array}{ccc} \mathcal{M}_1 \times_{\mathcal{M}_0} \mathcal{M}_1 \times X & \xrightarrow{\pi_i \times \text{id}_X} & \mathcal{M}_1 \times X \longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ (\pi_1, \pi_2) \times \text{id}_X \downarrow & & \downarrow p \\ \mathcal{M}_1 \times \mathcal{M}_1 \times X & & \\ (s, t) \times (s, t) \times \text{id}_X \downarrow & & \\ \mathcal{M}_0^4 \times X & & \\ \text{id} \times \Delta \downarrow & & \\ \mathcal{M}_0^4 \times X^4 & & \\ \simeq \downarrow & & \\ (\mathcal{M}_0 \times X)^4 & \xrightarrow{\text{pr}_i} & (\mathcal{M}_0 \times X)^2 \end{array}$$

where the right vertical map is the vector bundle projection and the bottom horizontal map is the projection of the product onto the first or last two factors. This yields canonical maps over B_X^4 of the form:

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \xrightarrow{\rho_i} \text{pr}_i^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

by the universal property of pullbacks. These, in turn, provide a canonical map:

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \xrightarrow{\rho} \text{pr}_1^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \times_{B_X^4} \text{pr}_2^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

because the codomain is a product in $\text{St}_{\mathcal{C}/B_X^4}$. Now, it is also the product in the essential image of $\mathcal{V}_{B_X^4}$ and thus is the direct sum. This gives us a canonical map:

$$\text{pr}_1^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \times_{B_X^4} \text{pr}_2^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \xrightarrow{m} \text{pr}_1^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X) \otimes \text{pr}_2^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

but the codomain is just $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \boxtimes \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$. Hence, we have constructed a map:

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \xrightarrow{m \circ \rho} \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \boxtimes \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$$

The issue, however, is that there is no immediate trace map $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \longrightarrow \mathcal{O}_{B_X^4}$. To get around this, we must utilize the fact that for composing two maps of vector bundles, the source of one must agree with the target of the

other. To achieve this, we pull back the bundle $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \boxtimes \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ along the map $\delta := (\text{id} \times \Delta_{B_X} \times \text{id}) : B_X \times B_X \times B_X \longrightarrow B_X \times B_X \times B_X \times B_X$:

$$\begin{array}{ccc} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \delta^* pr_2^* \mathcal{E}_X \otimes \delta^* pr_3^* \mathcal{E}_X^\vee \otimes \delta^* pr_4^* \mathcal{E}_X & \longrightarrow & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \boxtimes \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ \downarrow & \lrcorner & \downarrow \\ B_X^3 & \xrightarrow{\delta} & B_X^4 \end{array}$$

and observe that $pr_2 \circ \delta = pr_3 \circ \delta$ so that the middle two factors are of the form $E \otimes E^\vee$ for $E = \delta^* pr_2^* \mathcal{E}_X = \delta^* pr_3^* \mathcal{E}_X$. We further notice that the left vertical map of **3** factors through δ . This shows that the map $m \circ \rho$ factors through the above pullback. Hence, we have a map:

$$\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \xrightarrow{\rho'} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes E \otimes E^\vee \otimes \delta^* pr_4^* \mathcal{E}_X$$

Composing with the trace $\text{tr} : E \otimes E^\vee \longrightarrow \mathcal{O}_{B_X^3}$, we get a map

$$\begin{aligned} \mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X &\xrightarrow{c'} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \mathcal{O}_{B_X^3} \otimes \delta^* pr_4^* \mathcal{E}_X \\ &\xrightarrow{\simeq} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \delta^* pr_4^* \mathcal{E}_X \end{aligned}$$

Using the fact that $(pr_1, pr_4) \circ \delta = (pr_1, pr_3)$, we notice that the codomain of this map is the pullback

$$\begin{array}{ccc} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \delta^* pr_4^* \mathcal{E}_X & \longrightarrow & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ \downarrow & \lrcorner & \downarrow \\ B_X^3 & \xrightarrow{(pr_1, pr_3)} & B_X^2 \end{array}$$

giving us a map

$$\begin{aligned} \mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X &\xrightarrow{c'} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \mathcal{O}_{B_X^3} \otimes \delta^* pr_4^* \mathcal{E}_X \\ &\xrightarrow{\simeq} \delta^* pr_1^* \mathcal{E}_X^\vee \otimes \delta^* pr_4^* \mathcal{E}_X \\ &\longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \end{aligned}$$

which we will call c' .

Further straightforward verification shows that this map composed with the projection $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \longrightarrow B_X \times B_X$ factors through the map:

$$\begin{aligned} &\mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \times X \\ &\xrightarrow{(s,t) \times \text{id}_X} \mathcal{M}_{\text{Vect}(X)} \times \mathcal{M}_{\text{Vect}(X)} \times X \\ &\xrightarrow{\text{id} \times \Delta_X} \mathcal{M}_{\text{Vect}(X)}^2 \times X^2 \simeq B_X^2 \end{aligned}$$

This shows that c' corresponds to a map

$$c : \mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} \longrightarrow \mathcal{M}_{\text{Vect}(X),1}$$

which we take as our desired composition map. Finally, chasing U -points for arbitrary U as for the maps s, t, e before shows that, a U -point $f :$

$U \longrightarrow \text{dom}(c)$ corresponds to two triples $(E, F, f), (F, G, g)$ and $c \circ (f, g)$ corresponds to the triple $(E, G, g \circ f)$.

We can now collect the constructions and arguments above into the following theorem:

Theorem 3.3. *There exists a stack $\mathcal{M}_{\text{Vect}(X),1} \in \text{St}_{\mathcal{C}}$ along with maps*

$$\begin{aligned} s, t : \mathcal{M}_{\text{Vect}(X),1} &\longrightarrow \mathcal{M}_{\text{Vect}(X)} \\ e : \mathcal{M}_{\text{Vect}(X)} &\longrightarrow \mathcal{M}_{\text{Vect}(X),1} \\ c : \mathcal{M}_{\text{Vect}(X),1} \times_{\mathcal{M}_{\text{Vect}(X)}} \mathcal{M}_{\text{Vect}(X),1} &\longrightarrow \mathcal{M}_{\text{Vect}(X),1} \end{aligned}$$

If $\mathcal{C} = \text{CRing}^{\heartsuit, \text{op}}$ and we use the same symbols to denote the analogous constructions in $\text{St}_{\mathcal{C}}^1$, we have that

- (i) U -points of $\mathcal{M}_{\text{Vect}(X),1}$ are in bijection with triples (E, F, f) , for vector bundles E, F over $U \times X$ and a map of vector bundles $f : E \longrightarrow F$.
- (ii) Post-composition with s and t send a U -point f of $\mathcal{M}_{\text{Vect}(X),1}$ to U -points of $\mathcal{M}_{\text{Vect}(X)}$ corresponding to the domain and codomain of the map of vector bundles corresponding to f .
- (iii) Post-composition with e sends a U -point f of $\mathcal{M}_{\text{Vect}(X)}$ to the U -point of $\mathcal{M}_{\text{Vect}(X),1}$ corresponding to the identity map of the vector bundle classified by f .
- (iv) Post-composition with c sends a U -point f of $\text{dom}(c)$ given by two triples $(E, F, f), (F, G, g)$ to the triple $(E, G, g \circ f)$.
- (v) $(\mathcal{M}_{\text{Vect}(X)}, \mathcal{M}_{\text{Vect}(X),1}, s, t, e, c)$ forms an internal category in $\text{St}_{\mathcal{C},\tau}^1$.

Proof. Only the last point remains to be shown but this follows from the fact that for each U , we have a category object in Set given by

$$(\mathcal{M}_{\text{Vect}(X)}(U), \mathcal{M}_{\text{Vect}(X),1}(U), s, t, e, c)$$

□

Remark 3.4. This result is likely a categorical truncation of the 2-Segality established in [DPS25, Lemma II.4.1]

4. MODULI STACKS OF QUIVER BUNDLES

The stack $\mathcal{M}_{\text{Vect}(X),1}$ defined in the previous section is the moduli stack of quiver bundles for the quiver

$$\Delta^1 = \cdot \longrightarrow \cdot$$

In this section, we proceed to define moduli stacks of quiver bundles for more general quivers, using linear algebraic constructions on universal vector bundle as in the previous section. Let $\Delta^n = \text{Hom}_{\Delta}(-, [n]) \in \text{sSet}$ be the standard n -dimensional simplex. For brevity of notation, we will fix an object $X \in \text{St}_{\mathcal{C}}$ and denote $\mathcal{M}_0 := \mathcal{M}_{\text{Vect}(X)}, \mathcal{M}_1 := \mathcal{M}_{\text{Vect}(X),1}$. We will consider $n+1$ copies of \mathcal{M}_0 denoted $\mathcal{M}_{0,j}$ for $j = 0, 1, \dots, n$, and $\binom{n}{2}$ copies of \mathcal{M}_1 , denoted $\mathcal{M}_{1,(i,j)}$ for $i < j \in [n] = \{0, 1, \dots, n\}$. The moduli stack

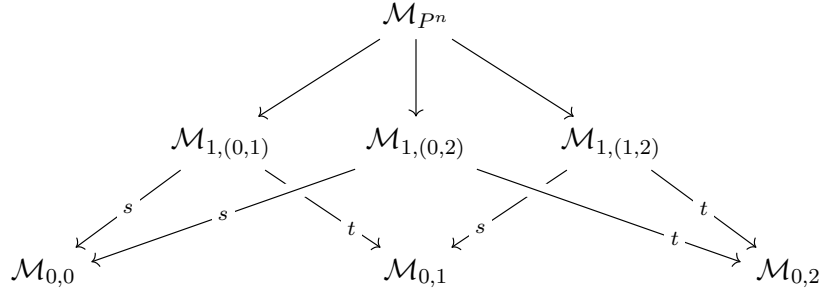

of non-commutative diagrams of vector bundles over X , indexed by the 1-skeleton P^n of Δ^n , should simply be the limit, denoted $\mathcal{M}_{\text{Vect}(X), P^n}$ or just \mathcal{M}_{P^n} , of the diagram in St_e formed by the vertices

$$\{\mathcal{M}_{1,(i,j)}\}_{i,j \in [n]} \cup \{\mathcal{M}_{0,i}\}_{i \in [n]}$$

and arrows:

$$\left\{ \mathcal{M}_{1,(i,j)} \xrightarrow{s} \mathcal{M}_{0,i} \right\}_{i,j \in [n]} \cup \left\{ \mathcal{M}_{1,(i,j)} \xrightarrow{t} \mathcal{M}_{0,j} \right\}_{i,j \in [n]}$$

For example, for $n = 2$, this limit diagram is as follows:

Now, consider any subset $S = \{k_0 < k_1 < \dots < k_m\} \subset [n]$. \mathcal{M}_{P^n} admits a canonical projection to the pullback:

$$\mathcal{M}_{1,(k_0,k_1)} \times_{\mathcal{M}_{0,k_1}} \mathcal{M}_{1,(k_1,k_2)} \times_{\mathcal{M}_{0,k_2}} \dots \times_{\mathcal{M}_{0,k_{m-1}}} \mathcal{M}_{1,(k_{m-1},k_m)}$$

which, in turn, admits a composition morphism to $\mathcal{M}_{1,(k_0,k_m)}$ by iterating composition morphism of Theorem 3.3.

Warning 4.1. This iterated composition morphism is defined up to contractible choice in the ∞ -categorical case.

This gives us maps of the following form for each such $S \subset [n]$:

$$c_S : \mathcal{M}_{P^n} \longrightarrow \mathcal{M}_{1,(k_0,k_m)}$$

We want all composites with the same source and target vertices to be equivalent and this yields the following definition.

Definition 4.2 (Moduli Stack of Standard Quiver Bundles). We define $\mathcal{M}_{\text{Vect}(X), \Delta^n}$ to be the pullback:

$$\begin{array}{ccc} \mathcal{M}_{\text{Vect}(X), \Delta^n} & \xrightarrow{\quad} & \mathcal{M}_{\text{Vect}(X), P^n} \\ \downarrow & \lrcorner & \downarrow \{c_S\}_{S \subset [n]} \\ \prod_{i < j \in [n]} \mathcal{M}_{1,(i,j)} & \xrightarrow{\Delta} & \prod_{i < j \in [n]} \prod_{\substack{S \subset [n], \\ \min S = i, \\ \max S = j}} \mathcal{M}_{1,(i,j)} \end{array}$$

where the bottom horizontal map is given by diagonal morphisms. We will call $\mathcal{M}_{\text{Vect}(X), \Delta^n}$ the moduli stack of standard n -quivers.

Let $\iota : [m] \longrightarrow [n]$ be an injection and consider the ordered set

$$J(i) = \{j_0 = \iota(i) < j_1 = \iota(i) + 1 < \cdots < j_k = \iota(i+1)\}$$

Consider the map $c_{J(i)} : \mathcal{M}_{P^n} \longrightarrow \mathcal{M}_{1,(j_0,j_k)} \simeq \mathcal{M}_{1,(i,i+1)}$ as defined before. The collection of these maps for all $i \in [m]$ induce a map $\mathcal{M}_{\text{Vect}(X),\iota} : \mathcal{M}_{P^n} \longrightarrow \mathcal{M}_{P^m}$, written \mathcal{M}_ι for brevity. Now, let $\sigma : \Delta^m \longrightarrow \Delta^n$ be a map corresponding to a surjection $\sigma : [q] \longrightarrow [n]$. We then have diagonal maps

$$\mathcal{M}_{0,i} \xrightarrow{\Delta} \prod_{i' \in \sigma^{-1}(i)} \mathcal{M}_{0,i'}$$

and maps

$$\begin{aligned} & \mathcal{M}_{1,(i,j)} \\ & \xrightarrow{(s,\text{id})} \mathcal{M}_{0,s(i)} \times \mathcal{M}_{1,(i,j)} \\ & \xrightarrow{(e,e,\dots,e) \times \text{id}} \prod_{i' \in \sigma^{-1}(i) \setminus \{\max \sigma^{-1}(i)\}} \mathcal{M}_{1,(i',i'+1)} \times \mathcal{M}_{1,(\max \sigma^{-1}(i)-1, \max \sigma^{-1}(i))} \end{aligned}$$

These induce a map $\mathcal{M}_\sigma : \mathcal{M}_{P^n} \longrightarrow \mathcal{M}_{P^q}$, again written $\mathcal{M}_{\text{Vect}(X),\sigma}$ for brevity. The motivation for the map \mathcal{M}_ι is that it sends a chain of n composable arrows of vector bundles to a chain of m composable arrows by composing subchains of arrows prescribed by the function ι . The motivation behind \mathcal{M}_σ is that it sends a chain of n composable arrows to a chain of q composable arrows by inserting identity morphisms in a pattern encoded by σ . In fact, it can be shown that the maps \mathcal{M}_ι and \mathcal{M}_σ induce corresponding canonical maps $\mathcal{M}_{\Delta^n} \longrightarrow \mathcal{M}_{\Delta^m}, \mathcal{M}_{\Delta^n} \longrightarrow \mathcal{M}_{\Delta^q}$, by using the universal property of pullbacks — the idea is: composing and inserting identities respects commutativity of diagrams. Finally, it can also be shown that the maps $\mathcal{M}_\iota \circ \mathcal{M}_\sigma = \mathcal{M}_{\sigma \circ \iota}$ whenever $\iota \circ \sigma$ exists and since the morphisms of the simplicial indexing category Δ can be factorized into injections and surjections, we have the following results:

Corollary 4.3. *The assignment $[n] \longmapsto \mathcal{M}_{\text{Vect}(X),\Delta^n}$ as defined above gives a simplicial object $\mathcal{M}_{\text{Vect}(X),-} : \Delta^{\text{op}} \longrightarrow \text{St}_{\mathcal{C}}$.*

Definition 4.4 (Moduli Stack of Quiver Bundles). We define a functor $\mathcal{M}_{\text{Vect}(X),-} : \text{sSet}^{\text{op}} \longrightarrow \text{St}_{\mathcal{C}}$ by right Kan extension of the functor of the previous corollary along the Yoneda embedding $\Delta^{\text{op}} \longrightarrow \text{sSet}^{\text{op}}$. Given a simplicial set $I \in \text{sSet}$, we define the stack $\mathcal{M}_{\text{Vect}(X),I}$ to be the moduli stack of quiver bundles of shape I .

Corollary 4.5. *In the context of the previous definition and in the case that $\mathcal{C} = \text{CRing}^{\heartsuit,\text{op}}$ and analogous constructions in $\text{St}_{\mathcal{C}}^1$, U -points of $\mathcal{M}_{\text{Vect}(X),I}$ correspond to diagrams of vector bundles over $U \times X$ indexed by I . If I is a quasicategory, then these are commutative diagrams.*

We now discuss a sufficient condition for moduli stacks of quiver bundles of finite shape (that is, indexed by finite simplicial sets) to be algebraic, by

which we mean Artin. We will only address the question of algebraicity for a class of base 1-stacks relevant for some applications we have in mind, and leave a comprehensive treatment for future work.

Lemma 4.6. *Let $\mathcal{D} \subset \text{St}_{\mathcal{C}, \tau}$ be a full subcategory of \mathcal{C} closed under pullbacks and containing the terminal object of \mathcal{C} . For any $X \in \text{St}_{\mathcal{C}}$, if $\mathcal{M}_{\text{Vect}(X)}$, $\text{Map}(X, B_X^2)$, $\text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$ are in \mathcal{D} , then for any finite simplicial set I , $\mathcal{M}_{\text{Vect}(X), I} \in \mathcal{D}$.*

Proof. For a finite simplicial set I , $\mathcal{M}_{\text{Vect}(X), I}$ is defined as a finite limit involving $\mathcal{M}_{\text{Vect}(X), 1}$ and $\mathcal{M}_{\text{Vect}(X)}$. On the other hand, $\mathcal{M}_{\text{Vect}(X), 1}$ is defined as a pullback involving $\mathcal{M}_{\text{Vect}(X)}^2$, $\text{Map}(X, B_X^2)$ and $\text{Map}(X, \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$. Hence, if these objects are in \mathcal{D} , then so is $\mathcal{M}_{\text{Vect}(X), 1}$ by the closure of \mathcal{D} under pullbacks. The result now follows from the fact that finite limits can be computed by using pullbacks and terminal objects. \square

Definition 4.7 (Stabilizers [Kha22, Definition 5.19]). Let $V \in \text{St}_{\mathcal{C}}$ and $x : A \rightarrow V$ be a point of V for $A \in \mathcal{C}$. The stabilizer of x is defined to one of following equivalent pullbacks:

$$\begin{array}{ccc} \text{Stab}_V(x) & \longrightarrow & A \\ \downarrow & \lrcorner & \downarrow x \\ A & \xrightarrow{x} & V \end{array} \qquad \begin{array}{ccc} \text{Stab}_V(x) & \longrightarrow & V \\ \downarrow & \lrcorner & \downarrow \Delta \\ A & \xrightarrow{(x,x)} & V \times V \end{array}$$

If for all x as above, $\text{Stab}_V(x)$ is in \mathcal{C} , then we say V has affine diagonal. In the case that \mathcal{C} is $\text{CRing}_{R/}^{\heartsuit, \text{op}}$, for some ring R , equipped with the fppf topology, we say that V has affine stabilizers if for all fields k and all maps $x : \text{Spec}(k) \rightarrow V$, $\text{Stab}_V(x)$ is an affine scheme (of course, over R).

Lemma 4.8. *For any diagram of stacks $Y \rightarrow W \leftarrow Z$, if Y, Z have affine diagonal, then so does $Y \times_W Z$. If Y, Z have affine stabilizers, then so does $Y \times_W Z$.*

Proof. For $A \in \text{CRing}_{R/}^{\heartsuit, \text{op}}$, and any point $x : A \rightarrow Y \times_W Z$, we have the two points $x_Y : A \xrightarrow{x} Y \times_W Z \rightarrow Y$, $x_Z : A \xrightarrow{x} Y \times_W Z \rightarrow Z$. We will show that

$$\text{Stab}_{Y \times_W Z}(x) \simeq \text{Stab}_Y(x_Y) \times_A \text{Stab}_Z(x_Z)$$

which is in \mathcal{C} because the Yoneda embedding $\mathcal{C} \hookrightarrow \text{St}_{\mathcal{C}}$ preserves limits. Let $f_Y : P \rightarrow \text{Stab}_Y(x_Y)$, $f_Z : P \rightarrow \text{Stab}_Z(x_Z)$ such that the following square commutes:

$$\begin{array}{ccc} P & \xrightarrow{f_Y} & \text{Stab}_Y(x_Y) \\ f_Z \downarrow & & \downarrow \\ \text{Stab}_Z(x_Z) & \longrightarrow & A \end{array}$$

This diagram can be extended to a commutative diagram:

$$\begin{array}{ccc}
 P & \xrightarrow{f_Y} & \mathrm{Stab}_Y(x_Y) \\
 f_Z \downarrow & & \downarrow \\
 \mathrm{Stab}_Z(x_Z) & \longrightarrow & A \\
 & \searrow & \downarrow x \\
 & & Y \times_W Z
 \end{array}$$

(Note: A curved arrow also points from $\mathrm{Stab}_Z(x_Z)$ to $Y \times_W Z$.)

This, in turn, gives a unique map $P \longrightarrow \mathrm{Stab}_{Y \times_W Z}(x)$ by the universal property of $\mathrm{Stab}_{Y \times_W Z}(x) = \lim(A \longrightarrow Y \times_W Z \longleftarrow A)$. This shows that $\mathrm{Stab}_{Y \times_W Z}(x)$ satisfies the universal property of $\mathrm{Stab}_Y(x_Y) \times_A \mathrm{Stab}_Z(x_Z)$, yielding the first claim. The same argument also proves the second claim by just taking A to be $\mathrm{Spec}(k)$ for an arbitrary field k . \square

Lemma 4.9. *For $(\mathcal{C}, \tau) = (\mathrm{CRing}_{R'}^{\heartsuit, \mathrm{op}}, \mathrm{fppf})$ and an affine morphism $f : W \longrightarrow Z$ in $\mathrm{St}_{\mathcal{C}}$, if Z has affine diagonal, then so does W . If Z has affine stabilizers, then so does W .*

Proof. Let $x : A \longrightarrow W$ be a morphism where $A \in \mathcal{C} = \mathrm{CRing}_{R'}^{\heartsuit, \mathrm{op}}$. We need to show that $Q := \mathrm{Stab}_W(x)$ is an affine scheme. This is equivalent to showing that the left vertical morphism in the following Cartesian square is affine for any ring R' :

$$\begin{array}{ccc}
 Q & \longrightarrow & W \\
 \downarrow & \lrcorner & \downarrow \Delta_W \\
 \mathrm{Spec}(R') & \xrightarrow{x} & W \times W
 \end{array}$$

This fits into the following commutative diagram:

$$\begin{array}{ccccc}
 & & Q & & \\
 & \swarrow & \downarrow & \searrow & \\
 P & & & & W \\
 \downarrow & \lrcorner & \downarrow & & \downarrow \Delta_W \\
 & & \text{Spec}(R') & & \\
 & \swarrow & \parallel & \searrow (x,x) & \\
 P' & & & & W \times W \\
 \downarrow & \lrcorner & \parallel & & \downarrow f \times f \\
 & & \text{Spec}(R') & & \\
 & \swarrow & \searrow (f \circ x, f \circ x) & & \\
 \text{Spec}(R') & \xrightarrow{(f \circ x, f \circ x)} & Z \times Z & &
 \end{array}$$

where the two front small squares and the back right top square are Cartesian — we have marked these with corners to indicate this — and where the maps $Q \rightarrow P$ and $\text{Spec}(R') \rightarrow P'$ are provided by the universal properties of the respective pullbacks. By the pullback pasting lemma, the back top left square is Cartesian. Then, by the fact that the class of affine morphisms are stable under base change [Sta25, Lemma 045C], it suffices to show that the morphism $P \rightarrow P'$ is affine.

For this, we first observe that P' is an affine scheme as f being affine implies $f \times f$ is affine [Sta25, Lemma 045E]. Next, we can show that P is also an affine scheme using the hypotheses that Z has affine diagonal and f is an affine morphisms along with the following commutative diagram:

$$\begin{array}{ccccc}
 P & \xrightarrow{\quad} & W & & \\
 \downarrow & \lrcorner & \downarrow \Delta_W & \searrow f & \\
 P' & \xrightarrow{\quad} & W \times W & & Z \\
 \downarrow & \lrcorner & \downarrow f \times f & \swarrow \Delta_Z & \\
 \text{Spec}(R') & \xrightarrow{(f \circ x, f \circ x)} & Z \times Z & &
 \end{array}$$

Since any morphism between affine schemes is affine, we have that $P \rightarrow P'$ is an affine morphism, as required.

The proof of the last claim is similar, with $\text{Spec}(R')$ replaced with $\text{Spec}(k)$ for a field k , and Z having an affine diagonal replaced with Z having affine stabilizers. \square

Theorem 4.10. *Let R be a ring and $(\mathcal{C}, \tau) = (\mathrm{CRing}_{R'}^{\heartsuit, \mathrm{op}}, \mathrm{fppf})$ and let $\mathrm{AlgSt}_{\mathcal{C}, \tau}$ be the full subcategory of Artin stacks. Let $X \longrightarrow \mathrm{Spec}(R) \in \mathrm{St}_{\mathcal{C}}^1$ satisfy the following:*

- (a) X is in $\mathrm{AlgSt}_{\mathcal{C}} = \mathrm{AlgSt}_{\mathcal{C}, \tau}$.
- (b) X is proper, flat, of finite presentation, and has affine stabilizers.
- (c) $\mathcal{M}_{\mathrm{Vect}(X)}$ is in $\mathrm{AlgSt}_{\mathcal{C}}$.
- (d) $\mathcal{M}_{\mathrm{Vect}(X)}$ is quasi-separated.
- (e) $\mathcal{M}_{\mathrm{Vect}(X)}$ is locally of finite presentation.
- (f) $\mathcal{M}_{\mathrm{Vect}(X)}$ has affine stabilizers.

Then, for any finite simplicial set I , $\mathcal{M}_{\mathrm{Vect}(X), I}$:

- (i) is in $\mathrm{AlgSt}_{\mathcal{C}}$ (i.e., is Artin),
- (ii) is locally of finite presentation
- (iii) is quasi-separated, and
- (iv) has affine stabilizers, and

if, furthermore, X and $\mathcal{M}_{\mathrm{Vect}(X)}$ have affine diagonal, then:

- (v) $\mathcal{M}_{\mathrm{Vect}(X), I}$ has affine diagonal.

Proof. Since X is of finite presentation by hypothesis, it is locally of finite presentation and quasi-separated, in particular. $\mathcal{M}_{\mathrm{Vect}(X)}$ is also locally of finite presentation and quasi-separated, by hypothesis. Thus, the product $B := (\mathcal{M}_{\mathrm{Vect}(X)} \times X)^2$ is quasi-separated and locally of finite presentation. In addition, since X and $\mathcal{M}_{\mathrm{Vect}(X)}$ have affine stabilizers, so does B , by Lemma 4.8. Denoting $\mathcal{E} := \mathcal{E}_X^{\vee} \boxtimes \mathcal{E}_X$, \mathcal{E} being affine over B now implies the following:

- (1) \mathcal{E} is algebraic by [Sta25, Lemma 05UM], as the morphism $p : \mathcal{E} \longrightarrow B$, being affine, is representable by algebraic spaces, and B is an algebraic stack.
- (2) \mathcal{E} has affine stabilizers by Lemma 4.9.
- (3) $\mathcal{E} \longrightarrow B$ is quasi-separated as an affine morphism is quasi-separated by [Sta25, Tag 01S7]. Therefore, it is quasi-separated over $\mathrm{Spec}(R)$ as the composite $\mathcal{E} \longrightarrow B \longrightarrow \mathrm{Spec}(R)$ of quasi-separated morphisms quasi-separated.

Next, \mathcal{E} being the relative spectrum of the symmetric algebra of a locally free sheaf over B implies the following:

- (4) \mathcal{E} is locally of finite presentation over B and hence over $\mathrm{Spec}(R)$.

These observations allow us to apply [HR19, Theorem 1.2(i)] to deduce that the mapping stacks $\mathrm{Map}(X, B_X^2)$ and $\mathrm{Map}(X, \mathcal{E}_X^{\vee} \boxtimes \mathcal{E}_X)$ are in $\mathrm{AlgSt}_{\mathcal{C}}$. Then, Lemma 4.6 implies (i).

For (ii), (iii), we observe that the properties involved are preserved by pullback and hence finite limits of stacks satisfying these two properties have them. The same holds for the property in (iv) by Lemma 4.8. So, it suffices to verify that the mapping stacks before have these properties, which follows by applying [HR19, Theorem 1.2(ii)].

For (v), we first prove that $\mathrm{Map}(X, B_X^2), \mathrm{Map}(X, \mathcal{E})$ have affine diagonals. To do so, it suffices to show that B_X^2 and \mathcal{E} have affine diagonals by [HR19, Theorem 1.2(iii)]. That B_X^2 has affine diagonal follows from the assumption that X and $\mathcal{M}_{\mathrm{Vect}(X)}$ have affine diagonal in combination with Lemma 4.8. That \mathcal{E} has affine diagonal then follows from Lemma 4.9 and the fact that B_X has affine diagonal. Furthermore, $\mathcal{M}_{\mathrm{Vect}(X)}^2$ has affine diagonal by Lemma 4.8 and the assumption that $\mathcal{M}_{\mathrm{Vect}(X)}$ has affine diagonal. By Lemma 4.8 yet again, it follows that $\mathcal{M}_{\mathrm{Vect}(X),1}$ has affine diagonal. Again, since $\mathcal{M}_{\mathrm{Vect}(X),I}$ is a finite limit computed using pullbacks involving the terminal object, $\mathcal{M}_{\mathrm{Vect}(X)}$ and $\mathcal{M}_{\mathrm{Vect}(X),1}$, which all have affine diagonal, Lemma 4.8 implies that $\mathcal{M}_{\mathrm{Vect}(X),I}$ has affine diagonal. \square

Corollary 4.11. *If X is a projective variety over a field, then for all finite simplicial sets I , $\mathcal{M}_{\mathrm{Vect}(X),I}$:*

- (1) *is Artin,*
- (2) *is locally of finite presentation, and*
- (3) *has affine diagonal (in particular, is quasi-separated).*

Proof. Being a projective variety, X satisfies all the hypotheses of Theorem 4.10. We then observe that $\mathcal{M}_{\mathrm{Vect}(X)} = \coprod_{n=0}^{\infty} \mathrm{Map}(X, B\mathrm{Gl}_n)$ is quasi-separated, locally of finite presentation, and has an affine diagonal by [Wan11, Theorem 1.0.1.], and hence satisfies all hypotheses of Theorem 4.10. \square

Remark 4.12. For algebraicity, the hypotheses of Theorem 4.10 are not the most relaxed possible: see Remark 1.1. However, the more constrained hypotheses allowed us to prove some additional properties of the diagonal of the constructed moduli stacks of quiver bundles that are not immediate from the results available in the literature on quiver bundles. Furthermore, it might be possible to use the same techniques of this paper to obtain similar or stronger results with more relaxed hypotheses. For instance, there are more general results available on algebraicity of mapping stacks in both the classical [AHR23, Theorem 6.22] and the derived settings [HP19, Theorem 5.1.1]. Furthermore, it might be possible to rephrase the stack $\mathcal{M}_{\mathrm{Vect}(X),1}$ as a Weil restriction involving $\mathcal{M}_{\mathrm{Vect}(X)}, X, \mathcal{E}_X^{\vee} \boxtimes \mathcal{E}_X$ or fibre products thereof (this was suggested to us by Daniel Halpern-Leistner at the 2nd Simons Math Summer Workshop on “Moduli” in July 2024). In this case, we might be able to use algebraicity results on Weil restrictions such as [HP19, Theorem 5.1.14] to further relax the conditions on X .

Remark 4.13 (Meaning of categorification). In the previous section, we constructed moduli stacks parametrizing the morphisms involved in the moduli problem for vector bundles. We have discussed how these morphism moduli stacks along with the original moduli stacks form internal categories. In this section, we have used that stack to construct an algebraic moduli stack parametrizing vector bundle diagrams of any fixed finite shape. In fact, given a simplicial set I , we can consider the moduli stack $\mathcal{M}_{\mathrm{Vect}(X),I \times \Delta^1}$ to be the moduli stack of morphisms of quiver bundles of shape I and it is not

much different to show that this forms an internal category. It is in this sense, that we have categorified the moduli problem of vector bundles as well as quiver bundles. That is, we have produced a notion of a category stack parametrizing these objects and their morphisms as opposed to just a single stack parametrizing the objects.

5. QUIVER VARIETIES

It is imperative from our title that we discuss how to recover quiver varieties and Nakajima quiver varieties from our framework and we now provide a sketch to accomplish this. We emphasize that some of the statements made in this section are conjectural and we hope we have made it clear when it is. We intend to complete this work in a future paper.

5.1. Quiver Stacks and Quiver Varieties. Pick any quiver I in the usual sense of quiver theory — this is a simplicial set with no 2-simplices. Assuming we are working over a base ring k , take for the base space X , the point $\mathrm{Spec}(k)$. Then, vector bundles over X are the affine schemes over k and $\mathcal{M}_{\mathrm{Vect}(X),I}$ is the representation stack $\mathrm{Rep}(I)$. The difference is that for constructing the classical representation space, one needs to choose dimension vectors in order to write down the space as a direct sum of vector space Hom 's. The stack $\mathcal{M}_{\mathrm{Vect}(X),I}$ parametrizes all finite dimensional representations irrespective of dimension vectors. One might then try to translate the group action used in quiver theory to construct quiver varieties to a group action on this stack and then take a GIT quotient as the quiver variety. However, we will phrase the construction using simplicial language. That is, we will construct a different simplicial set \tilde{I} whose representations in $\mathrm{Vect}(\mathrm{Spec}(k))$ correspond to triples (g, ρ, ψ) , where g is an element of the automorphism group of representations of I , and ρ and ψ are representations of I , such that $g \cdot \rho = \psi$. Roughly speaking, \tilde{I} will contain two copies of I joined at the corresponding vertices with a pair of oppositely directed edges and a pair of 2-simplices encoding that they are isomorphisms. For each edge $e \in I$, denoting its second copy in \tilde{I} as e' , and the two edges $g_{0,e} : d_0 e \rightarrow d_0 e'$ and $g_{1,e'} : d_1 e \rightarrow d_1 e'$ in \tilde{I} , we will have two 2-simplices encoding the relation $g_{1,e'} e = e' g_{0,e}$. If the quiver I has framing nodes, we have to be slightly more careful.

We now give a more explicit construction. First, framing nodes can be encoded as a function $f : I_0 \rightarrow \{0, 1\}$, where $f^{-1}(0)$ are the usual nodes and $f^{-1}(1)$ are the framing nodes. The vertex set of \tilde{I} is then defined to be:

$$\tilde{I}_0 := f^{-1}(0) \amalg f^{-1}(0) \amalg f^{-1}(1)$$

which has two copies of each regular node of I and one copy of each framing node. To describe the edge set, first consider the set $S := (fd_0, fd_1)^{-1}(1, 1)$ of edges whose source and target are both framing nodes, and the set $I_1 \setminus S$ of edges which has a source or a target that is not a framing node. For each

regular node $v \in f^{-1}(0)$, we consider symbols g_v, g_v^{-1} , and define

$$T := \{g_v : v \in f^{-1}(0)\} \amalg \{g_v^{-1} : v \in f^{-1}(0)\}$$

These are to be thought of as isomorphism edges going from one copy of v to another in \tilde{I} . For $e \in I_1 \setminus S$, we also consider tuples $(g_{d_1(e)}, e)$ and think of them as the composite $g_{d_1(e)} \circ e$. We write:

$$T' := \{(g_v, e) : e \in I_1 \setminus S, v = d_1(e)\}$$

Then, we define the edge set to be:

$$\tilde{I}_1 := (I_1 \setminus S) \amalg (I_1 \setminus S) \amalg S \amalg T \amalg T'$$

where the two copies of $I_1 \setminus S$ consist of two copies of each edge in I incident to a regular node, S consists of one copy of each edge incident to framing nodes, and T consists of the isomorphism edges connecting the two copies of each regular node, T' consists of composites of edges between regular nodes and isomorphism edges. We leave it to the reader to define the face and degeneracy maps to make these ideas precise.

Next, we describe the 2-simplices of \tilde{I} which impose the necessary relations. For each $v \in f^{-1}(0)$, denoting its second copy in \tilde{I} as v' , we consider 2-simplices of the form:

$$\alpha_v := \begin{array}{ccc} & v & \\ \parallel & \searrow g_v & \\ v & \xleftarrow{g_v^{-1}} & v' \end{array} \qquad \beta_v := \begin{array}{ccc} & v' & \\ g_v^{-1} \swarrow & \parallel & \searrow \\ v & \xrightarrow{g_v} & v' \end{array}$$

For $e \in (fd_0, fd_1)^{-1}(0, 0) \subset I_1 \setminus S$ — that is, an edge incident to no framing nodes — we denote its second copy in \tilde{I}_1 as e' , and we consider 2-simplices that glue to squares of the form:

$$\gamma_e := \begin{array}{ccc} d_0(e) & \xrightarrow{e} & d_1(e) \\ \downarrow g_{d_0(e)} & \searrow (g_{d_1(e)}, e) & \downarrow g_{d_1(e)} \\ d_0(e') & \xrightarrow{e'} & d_1(e') \end{array}$$

We call the upper right 2-simplex α_e and the lower left 2-simplex β_e .

For $e \in (fd_0, fd_1)^{-1}(0, 1) \subset I_1 \setminus S$ — that is, an edge with a framing node as a target — we again denote its second copy in \tilde{I} as e' , and consider

a 2-simplex of the form:

$$\begin{array}{ccc}
 d_0(e) & & \\
 \downarrow \delta_e := g_{d_0(e)} & \searrow e & \\
 & d_1(e) = d_1(e') & \\
 & \nearrow e' & \\
 d_0(e') & &
 \end{array}$$

For $e \in (fd_0, fd_1)^{-1}(1, 0)$, we consider a similar simplex:

$$\begin{array}{ccc}
 & & d_1(e) \\
 & \nearrow e & \downarrow g_{d_1(e)} \\
 \epsilon_e := d_0(e) = d_0(e') & & \\
 & \searrow e' & \\
 & & d_1(e')
 \end{array}$$

We then define:

$$\begin{aligned}
 \tilde{I}_2 := & \{ \alpha_v : v \in f^{-1}(0) \} \amalg \{ \beta_v : v \in f^{-1}(0) \} \\
 & \amalg \{ \gamma_e : e \in (fd_0, fd_1)^{-1}(0, 0) \} \\
 & \amalg \{ \delta_e : e \in (fd_0, fd_1)^{-1}(0, 1) \} \amalg \{ \epsilon_e : e \in (fd_0, fd_1)^{-1}(1, 0) \}
 \end{aligned}$$

The face and degeneracy maps are the obvious ones. Finally, we define the higher $\tilde{I}_n, n > 2$ to only consist of degenerate simplices. A point to note here is that this construction of \tilde{I} is only simplicial, and highly non-categorical. In particular, \tilde{I} does not have simplices to witness composites of all composable chains of arrows, it only has enough 2-simplices to encode the equivalence relation given by the group action on the representation space of I . However, we note that quiver theory requires this non-categorical aspect: the quiver I we begin with is not a category and its representations are not functors, but maps of simplicial sets $I \longrightarrow \text{Vect}(\text{Spec}(k))$; furthermore, the equivalence relation given by the group action on representations selectively takes into account composites of arrows.

Example 5.1. Let I be the graph:

$$a \xrightarrow{e_{ab}} b \xrightarrow{e_{bc}} c$$

where a, b are regular nodes — $f(a) = 0 = f(b)$ — and c is a framing node — $f(c) = 1$. Then, \tilde{I} is a simplicial set of the form (not a category!):

$$\begin{array}{ccccc}
 a & \xrightarrow{e_{ab}} & b & & \\
 \uparrow g_a & & \uparrow g_b & \searrow e_{bc} & \\
 & & & & c \\
 \downarrow g_a^{-1} & & \downarrow g_b^{-1} & \nearrow e'_{bc} & \\
 a' & \xrightarrow{e'_{ab}} & b' & &
 \end{array}$$

where we have 2-simplices witnessing the identities $g_a^{-1}g_a = \text{id}_a$, $g_b^{-1}g_b = \text{id}_b$, $g_ag_a^{-1} = \text{id}_{a'}$, $g_bg_b^{-1} = \text{id}_{b'}$, $g_be_{ab} = e'_{ab}g_a$, $e'_{bc}g_b = e_{bc}$, but no 2-simplex witnessing a composite $e_{bc}e_{ab}$, for example.

Remark 5.2. It is likely that there is a more “invariant” way to construct the graph \tilde{I} or another one categorically equivalent to it (note that categorical equivalence makes sense for simplicial sets and not just quasicategories) as a colimit involving I and its simplicial subsets, so that its representations encode the group action in a similar way. However, we will not pursue this idea for now.

With this setup, we observe that we have two obvious inclusions $\iota, \kappa : I \longrightarrow \tilde{I}$ and we can define the moduli stack of quiver representations to be the $(2, 1)$ -coequalizer

$$\text{Quiver}(I) := \text{colim} \left(\mathcal{M}_{\text{Vect}(X), \tilde{I}} \begin{array}{c} \xrightarrow{\mathcal{M}_{\text{Vect}(X), \iota} \\ \xleftarrow{\mathcal{M}_{\text{Vect}(X), \kappa}} \end{array} \mathcal{M}_{\text{Vect}(X), I} \right)$$

Then, one can hope to apply “Beyond GIT” in the sense of [Hal22; AHH23] to recover quiver varieties in the usual sense, but these will be quiver varieties with respect to all choices of dimension vectors, and hence a disjoint union of quiver varieties for each choice of dimension vector.

5.2. Nakajima Quiver Varieties. Next, we would like to recover Nakajima quiver varieties, as originally introduced in [Nak94], out of our framework. The first step towards this is to add framing nodes for each vertex. We accomplish this by first gluing a copy of the graph:

$$0 \longrightarrow 1$$

to I at each vertex v , where v and 0 are identified. This can be realized as the strict pushout of simplicial sets:

$$\begin{array}{ccc}
 \text{sk}_0 I & \longrightarrow & I \\
 \downarrow & & \downarrow \\
 \coprod_{v \in I_0} (0 \longrightarrow 1) & \longrightarrow & I^{\text{fr}}
 \end{array}$$

where $\text{sk}_0 I$ is the 0-skeleton of I or the discrete simplicial set consisting of the vertices of I , and the left vertical map sends a vertex v to the source

vertex of the copy of $0 \longrightarrow 1$ corresponding to v . The next step is to double the edges, as they say in quiver theory. Given a quiver J , we take its double to be the strict pushout:

$$\begin{array}{ccc} \mathrm{sk}_0 J \simeq \mathrm{sk}_0 J^{\mathrm{op}} & \longrightarrow & J \\ \downarrow & \lrcorner & \downarrow \\ J^{\mathrm{op}} & \longrightarrow & d(J) \end{array}$$

Indeed, this takes a copy of J and a copy of J^{op} and glues them together at the vertex set. We are then interested in the representations of $d(I^{\mathrm{fr}})$ but those in the zero locus of the natural moment maps or so-called preprojective conditions¹. Moment maps are written using composition, direct sum, addition, and scaling (by constants) of linear maps indexed by arrows in the quiver whose representation we are considering. While it is easy to handle composition in our language, it is not clear how one should formalize direct sums, addition, subtraction, scaling. As a start, we can treat direct sums in much the same way as the map \otimes_1 in Guess 6.2, giving a map:

$$\oplus_1 : \mathcal{M}_{\mathrm{Vect}(X),1} \times \mathcal{M}_{\mathrm{Vect}X,1} \longrightarrow \mathcal{M}_{\mathrm{Vect}(X),1}$$

which sends a pair of morphisms to their direct sums. For the rest, we can first observe that, when X is a stack over k , for each $\lambda \in k$, there are maps:

$$s_\lambda : \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$$

that, viewing the domain and codomain as the respective sheaves of k -modules, scales a section by λ , and

$$+ : \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \oplus \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$$

that sends two sections to their sum. Some formal arguments are then necessary to show that these yield maps of moduli stacks:

$$s_\lambda : \mathcal{M}_{\mathrm{Vect}(X),1} \longrightarrow \mathcal{M}_{\mathrm{Vect}(X),1}$$

¹If $x \in \mathrm{Hom}(\mathbb{C}^s, \mathbb{C}^t)$ is a representation of an arrow in J and if $y \in \mathrm{Hom}(\mathbb{C}^t, \mathbb{C}^s)$ is a representation of its reversed-orientation counterpart in J^{op} , then there is an identification of y with a unique element in $T_x^* \mathrm{Hom}(\mathbb{C}^s, \mathbb{C}^t)$, coming from the trace pairing, where T_x^* refers to the (algebraic) cotangent space at x . Working over \mathbb{C} , these pairings allow us to find within the Nakajima quiver variety an open dense subset that may be identified with the (geometric) cotangent bundle of the ordinary quiver variety (associated to J), and the moment map conditions equip the Nakajima quiver variety with quaternionically-commuting complex structures and corresponding symplectic forms, all of which are compatible with a metric inherited by the quotient (cf. [Hit+87; Nak94]). This package of differential-geometric data is the so-called hyperkähler structure. One of these complex structures extends the one on the cotangent bundle uniquely. This feature is essential in many of the applications of Nakajima quiver varieties — for example, in integrable systems [RS20]. Finally, it is worth remarking that satisfying the moment map conditions is the GIT stability condition for this moduli problem.

that scales a morphism of vector bundles over X by λ , and for each graph of the forms:

$$J = \cdot \begin{array}{c} \xrightarrow{a} \\ \xleftarrow{b} \end{array} \cdot \quad \text{or} \quad J = a \curvearrowright \cdot \curvearrowleft b$$

a map:

$$+ : \mathcal{M}_{\text{Vect}(X), J} \longrightarrow \mathcal{M}_{\text{Vect}(X), 1}$$

that sends the morphisms indexed by a and b to their sum. One can then see that that this is enough to write down moment maps using only the moduli stacks we have constructed, by taking the various projections $\mathcal{M}_{\text{Vect}(X), d(I^{\text{fr}})} \longrightarrow \mathcal{M}_{\text{Vect}(X), K}$ for various choices of simplicial subsets $K \subset I$ along with the maps $\oplus_1, s_\lambda, +$ discussed above and the composition map c of Theorem 3.3. One then argues that moment maps will be of the form

$$\mu : \mathcal{M}_{\text{Vect}(X), d(I^{\text{fr}})} \longrightarrow \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1}$$

We can compare this with moment maps in usual quiver theory — they take values in the endomorphism spaces of the vector spaces in a representation. In our case, for each vertex $v \in I_0$, we have a copy of $\mathcal{M}_{\text{Vect}(X), 1}$ which, in particular, also has the endomorphisms.

To take a zero locus, one first needs a map

$$0 : \text{pt} \longrightarrow \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1}$$

that picks out the zero maps of vector bundles. We claim that the zero section of $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ can be used to construct such a map. The zero locus of the moment maps is then simply the pullback of stacks:

$$\begin{array}{ccc} Z_\mu & \xrightarrow{\quad} & \mathcal{M}_{\text{Vect}(X), d(I^{\text{fr}})} \\ \downarrow & \lrcorner & \downarrow \mu \\ \text{pt} & \xrightarrow[0]{} & \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1} \end{array}$$

We then consider the following diagram:

$$\begin{array}{ccccc} \mathcal{M}_{\text{Vect}(X), \widetilde{d(I^{\text{fr}})}} & \xrightarrow[\mathcal{M}_{\text{Vect}(X), \kappa}]{\mathcal{M}_{\text{Vect}(X), \iota}} & \mathcal{M}_{\text{Vect}(X), d(I^{\text{fr}})} & \xrightarrow{!} & \text{Quiver}(d(I^{\text{fr}})) \\ & & \searrow \mu & & \downarrow \mu' \\ & & & & \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1} \end{array}$$

where, if we can show that $\mu \circ \mathcal{M}_{\text{Vect}(X), \iota} \simeq \mu \circ \mathcal{M}_{\text{Vect}(X), \kappa}$, we obtain a unique-up-to-2-isomorphism map μ' , shown as a dashed arrow, making the right-most triangle commute. This is the analogue of the moment map being invariant with respect to the group action whose quotient gives the

Nakajima quiver variety in the usual theory. Here, of course, ι and κ are the two inclusions $d(I^{\text{fr}}) \hookrightarrow \widetilde{d(I^{\text{fr}})}$ and $!$ is the canonical map to the coequalizer. Once we have this, since taking pullbacks is functorial, we get the following commutative diagram:

$$\begin{array}{ccccc}
Z_\mu & \xrightarrow{\quad} & \mathcal{M}_{\text{Vect}(X), d(I^{\text{fr}})} & & \\
\downarrow & \searrow & \downarrow \mu & \searrow ! & \\
& & Z_{\mu'} & \xrightarrow{\quad} & \text{Quiver}(d(I^{\text{fr}})) \\
\downarrow & & \downarrow & & \downarrow \mu' \\
pt & \xrightarrow{\quad} & \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1} & & \\
\parallel & & \parallel & & \\
pt & \xrightarrow{\quad} & \prod_{v \in I_0} \mathcal{M}_{\text{Vect}(X), 1} & &
\end{array}$$

We can then hope to show that $Z_{\mu'}$ is equivalent as a stack to the classical Nakajima quiver variety associated to I .

5.3. Quiver Mutations. The constructions discussed here and the construction of the moduli stack of Higgs bundles we give in the next section can be described as using the internal category structure of the moduli stacks $\mathcal{M}_{\text{Vect}(X), 1}$ and $\mathcal{M}_{\text{Vect}(X)}$ to construct a moduli stack of quiver bundles for a different shape of quiver. That is, the integrability condition for Higgs bundles has a natural formulation in terms of taking a quiver of one shape and constructing another one using some operations available. This is reminiscent of quiver mutations appearing in representation theory. It is natural to ask, given two quivers I, J and a quiver mutation μ that takes I to J , if we can associate a morphism of stacks $\hat{\mu} : \mathcal{M}_{\text{Vect}(X), I} \longrightarrow \mathcal{M}_{\text{Vect}(X), J}$. If quiver mutations can be written down in terms of morphisms of simplicial sets, then we would get a map in the opposite direction, by the fact that $\mathcal{M}_{\text{Vect}(X), -}$ is a functor $\text{sSet}^{\text{op}} \longrightarrow \text{St}_c$ by definition. Whether or not quiver mutations can be expressed in the language of simplicial maps, it might still be interesting to try and construct maps associated to μ in either direction by hand.

6. HIGGS BUNDLES

We now discuss an application of the construction of the moduli stacks of quiver bundles from Section 4 in constructing a moduli stack parametrizing Higgs bundles and a moduli stack parametrizing morphisms thereof — one of the main motivations of this paper. This is where we categorify the moduli problem for Higgs bundles in the sense of Remark 4.13. We then discuss

non-Abelian Hodge theory in this categorified setting. For this section, we will only deal with $\mathrm{St}_{\mathrm{CRing}^{\heartsuit, \mathrm{op}}}^1$.

6.1. Moduli Stack of Higgs Bundles. We recall the definition of a Higgs bundle for which we refer the reader to [GR15, Example 9] for details in a context that coincides fairly readily with our setting here. Let $X \in \mathrm{St}_{\mathrm{CRing}^{\heartsuit, \mathrm{op}}}^1$ and K , a locally free \mathcal{O}_X -module equipped with an exterior product $\wedge : K \otimes_{\mathcal{O}_X} K \longrightarrow K \wedge K$. A K -twisted Higgs bundle over X is a pair $(E, \phi : E \longrightarrow E \otimes_{\mathcal{O}_X} K)$ such that the following diagram commutes:

$$(4) \quad \begin{array}{ccc} E & \xrightarrow{\phi} & E \otimes K \\ \downarrow & & \downarrow \phi \otimes \mathrm{id}_K \\ & & E \otimes K \otimes K \\ & & \downarrow \mathrm{id}_E \otimes \wedge \\ 0 & \longrightarrow & E \otimes K \wedge K \end{array}$$

We call the commutativity of this diagram the integrability condition. We call E the underlying bundle of the Higgs bundle and ϕ , the Higgs field. A morphism of K -twisted Higgs bundles $(E, \phi) \longrightarrow (E', \phi')$ is a vector bundle map $f : E \longrightarrow E'$ making the following diagram commute:

$$(5) \quad \begin{array}{ccc} E & \xrightarrow{\phi} & E \otimes K \\ f \downarrow & & \downarrow f \otimes \mathrm{id}_K \\ E' & \xrightarrow{\phi'} & E' \otimes K \end{array}$$

In other words, the data of a Higgs bundle amounts to a commutative diagram of the form 4, from which we can extract the underlying bundle by taking the top-left vertex and the Higgs field, by taking the top horizontal edge. Hence, the moduli stack of Higgs bundles should be a substack of the moduli stack of quiver bundles of shape

$$(6) \quad P := \begin{array}{ccc} a & \xrightarrow{e_{ab}} & b \\ \downarrow e_{ab'} & & \downarrow e_{bc} \\ & & c \\ & & \downarrow e_{cd} \\ b' & \xrightarrow{e_{b'd}} & d \end{array}$$

satisfying:

- (i) The vertex indexed by b is the one indexed by a tensored with E .
- (ii) The vertex indexed by c is the one indexed by b tensored with K .
- (iii) The vertex indexed by d is the one indexed by a tensored with $K \wedge K$.
- (iv) The vertex indexed by b' is 0.
- (v) The edge indexed by e_{bc} is the one indexed by e_{ab} tensored with id_K .
- (vi) The edge indexed by e_{cd} is the identity of vertex indexed by a tensored with \wedge .

(vii) The edges indexed by $e_{ab'}$ and $e_{b'd}$ are the unique maps.

Notice that (iv), (v) and (vi) imply the rest. We will use this observation to recover our desired substack as a pullback of maps out of $\mathcal{M}_{\text{Vect}(X),P}$ into some algebraic stacks, because, that would yield algebraicity immediately, as long as the hypotheses of Theorem 4.10 are satisfied.

There is a construction of the moduli stack of Higgs bundles given in [CW17, §7.4] whose description of points partially motivates our construction. A U -point of this moduli stack consists of a pr_2^*K -twisted Higgs bundle $(E, \phi : E \rightarrow E \otimes_{\mathcal{O}_{U \times X}} pr_2^*K)$ where $pr_2 : U \times X \rightarrow X$ is the second projection — note that pullback functors for sheaves are symmetric monoidal, they preserve colimits as they are left adjoint to pushforward functors, and hence, they preserve exterior algebra objects so that the diagrams defining Higgs bundles make sense for pr_2^*K . To construct our stack such that its points coincide with that of [CW17, §7.4], we will need a few results to define the maps that will cut it out.

Lemma 6.1. *Consider the map $p_f : \text{pt} \rightarrow \mathcal{M}_{\text{Vect}(X),1}$ corresponding to a triple $(E, F, f : E \rightarrow F)$ over X . Let $I \in \text{sSet}$, $s : \Delta^1 \rightarrow I$ be a 1-simplex and $\mathcal{M}_{\text{Vect}(X),s} : \mathcal{M}_{\text{Vect}(X),I} \rightarrow \mathcal{M}_{\text{Vect}(X),\Delta^1} \simeq \mathcal{M}_{\text{Vect}(X),1}$, the map given by the functor of Definition 4.4 applied to s . Then, the pullback stack:*

$$\begin{array}{ccc} \mathcal{M}_{\text{Vect}(X),I,s} & \longrightarrow & \mathcal{M}_{\text{Vect}(X),I} \\ \downarrow & \lrcorner & \downarrow \mathcal{M}_{\text{Vect}(X),s} \\ \text{pt} & \xrightarrow{p_f} & \mathcal{M}_{\text{Vect}(X),1} \end{array}$$

has U -points corresponding to quiver bundles of shape I whose edge given by s is pr_2^*f , where $pr_2 : U \times X \rightarrow X$ is the second projection.

Proof. A U -point of this pullback stack is a U -point of $\mathcal{M}_{\text{Vect}(X),I}$ that corresponds to an I -indexed quiver bundle whose edge given by s is a U -point $q : U \rightarrow \mathcal{M}_{\text{Vect}(X),1}$ that factors through p_f . p_f corresponds to a map $p'_f : X \simeq \text{pt} \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ such that $p \circ p'_f : X \rightarrow B_X^2$ factors through the map $(u_E, u_F) \times \Delta_X : X \simeq \text{pt} \times X \rightarrow \mathcal{M}_{\text{Vect}(X)}^2 \times X^2 \simeq B_X^2$, where $u_E, u_F : \text{pt} \rightarrow \mathcal{M}_{\text{Vect}(X)}$ are the maps corresponding to the vector bundles $E, F \rightarrow X$. Then, $q : U \rightarrow \mathcal{M}_{\text{Vect}(X),1}$ corresponds to a map $q' : U \times X \rightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ such that $p \circ q'$ is of the form $(q'_1 \times \text{id}_X, q'_3 \times \text{id}_X)$, where q'_i is the composite $U \times X \xrightarrow{q'} \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \xrightarrow{p} B_X^2 \xrightarrow{pr_i} \mathcal{M}_{\text{Vect}(X)}$, for $i = 1, 3$. Thus, q' defines a section of

$$(q'_1 \times \text{id}_X, q'_3 \times \text{id}_X)^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

which corresponds to a triple $(E', F', f' : E' \rightarrow F')$ over $U \times X$. Under the Cartesian closed structure of stacks, q factoring through p_f is equivalent to

q' factoring through p'_f as shown below:

$$\begin{array}{ccc} U \times X & \xrightarrow{q'} & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ \downarrow !\times \text{id}_X & \searrow pr_2 & \uparrow p'_f \\ \text{pt} \times X & \xrightarrow{\simeq} & X \end{array}$$

That is, q'_i is the composite $U \times X \xrightarrow{pr_2} X \xrightarrow{p'_f} \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \xrightarrow{p} B_X^2 \xrightarrow{pr_i} \mathcal{M}_{\text{Vect}(X)}$ for $i = 1, 3$. This implies that the section that defines (E', F', f') is a section of

$$((pr_1 \circ p \circ p'_f \circ pr_2) \times \text{id}_X, (pr_3 \circ p \circ p'_f \circ pr_2) \times \text{id}_X)^*(\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X)$$

which implies that (E', F', f') is actually of the form:

$$(pr_2^*E, pr_2^*F, pr_2^*f : pr_2^*E \longrightarrow pr_2^*F)$$

because $p \circ p'_f \simeq (u_E, u_F) \times \Delta_X \simeq (u_E \times \text{id}_X, u_F \times \text{id}_X)$. \square

Guess 6.2. *There exist maps*

$$\begin{aligned} - \otimes_0 - &: \mathcal{M}_{\text{Vect}(X)} \times \mathcal{M}_{\text{Vect}(X)} \longrightarrow \mathcal{M}_{\text{Vect}(X)} \\ - \otimes_1 - &: \mathcal{M}_{\text{Vect}(X),1} \times \mathcal{M}_{\text{Vect}(X),1} \longrightarrow \mathcal{M}_{\text{Vect}(X),1} \end{aligned}$$

such that

- (i) \otimes_0 sends U -points corresponding to two vector bundles E, F over $U \times X$ to a U -point corresponding to the vector bundle $E \otimes_{\mathcal{O}_{U \times X}} F$.
- (ii) \otimes_1 sends a U -point corresponding to two triples

$$(E, F, f : E \longrightarrow F), (E', F', f' : E' \longrightarrow F')$$

to a U -point corresponding to the triple

$$(E \otimes_{\mathcal{O}_{U \times X}} F, E' \otimes_{\mathcal{O}_{U \times X}} F', f \otimes_{\mathcal{O}_{U \times X}} f' : E \otimes_{\mathcal{O}_{U \times X}} F \longrightarrow E' \otimes_{\mathcal{O}_{U \times X}} F)$$

- (iii) Without making it fully precise, we also guess that these two maps make the internal category $(\mathcal{M}_{\text{Vect}(X)}, \mathcal{M}_{\text{Vect}(X),1}, s, t, e, c)$ of Theorem 3.3 into an internal symmetric monoidal category in $\text{St}_{\text{CRing}^\vee, \text{op}}^1$. For precise definitions, we refer the reader to [Ghi19, §1.3]. In particular, for each $U \in \text{St}_{\text{CRing}^\vee, \text{op}}^1$, the U -points of this internal category form a symmetric monoidal category.

Proof sketch. The map \otimes_0 is just the tensor product functor on the groupoid $\mathcal{M}_{\text{Vect}(X)}(U)$ of vector bundles over $U \times X$, for each affine scheme U . Now, the objects of $\mathcal{M}_{\text{Vect}(X),1}(U)$ are triples (E, F, f) for vector bundles E, F and a morphism of vector bundles $f : E \longrightarrow F$ over $U \times X$. We claim that a morphism $(E, F, f) \longrightarrow (E', F', f')$ in $\mathcal{M}_{\text{Vect}(X),1}(U)$ is a pair of vector

bundle isomorphism $a : E \longrightarrow E'$, $b : F \longrightarrow F'$, making the following square commute:

$$\begin{array}{ccc} E & \xrightarrow{f} & F \\ a \downarrow & & \downarrow b \\ E' & \xrightarrow{f'} & F' \end{array}$$

To see this, consider the maps $q, q' : U \times X \longrightarrow \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$ corresponding to the triples $(E, F, f), (E', F', f')$ and the four maps $q_1, q_2, q'_1, q'_2 : U \times X \longrightarrow \mathcal{M}_{\text{Vect}(X)}$ obtained by composing with the two maps $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \xrightarrow{p} B_X^2 \xrightarrow{pr_i} \mathcal{M}_{\text{Vect}(X)}$ for $i = 1, 3$ respectively, and observe that any natural transformation:

$$\begin{array}{ccc} & q & \\ U \times X & \xrightarrow{\quad} & \mathcal{E}_X^\vee \boxtimes \mathcal{E}_X \\ & q' & \end{array} \quad \begin{array}{c} \alpha \\ \parallel \\ \alpha \end{array}$$

gives two natural transformations $\alpha_1 : q_1 \implies q'_1, \alpha_2 : q_2 \implies q'_2$. This gives two vector bundle maps $a : E \longrightarrow E', b : F \longrightarrow F'$. One then has to verify that the maps f, f', a, b form a commutative square as above. With this, the map $\otimes_1 : \mathcal{M}_{\text{Vect}(X),1}(U) \times \mathcal{M}_{\text{Vect}(X),1} \longrightarrow \mathcal{M}_{\text{Vect}(X),1}$ is given by:

$$\begin{aligned} ((E, F, f), (E', F', f')) &\longmapsto (E \otimes E, F \otimes F', f \otimes f') \\ \left(\begin{array}{ccc} E & \xrightarrow{f} & F \\ a \downarrow & & \downarrow b \\ E' & \xrightarrow{f'} & F' \end{array}, \begin{array}{ccc} V & \xrightarrow{g} & W \\ c \downarrow & & \downarrow d \\ V' & \xrightarrow{g'} & W' \end{array} \right) &\longmapsto \begin{array}{ccc} E \otimes V & \xrightarrow{f \otimes g} & F \otimes W \\ a \otimes c \downarrow & & \downarrow b \otimes d \\ E' \otimes V' & \xrightarrow{f' \otimes g'} & F' \otimes W' \end{array} \end{aligned}$$

It remains to describe what \otimes_1 does to morphisms in $\mathcal{M}_{\text{Vect}(X),1}$ that do not lie above identity morphisms of affine schemes. In this case, consider a morphism $u : U \longrightarrow U'$ of affine schemes. A morphism above this in $\mathcal{M}_{\text{Vect}(X),1}$ is just a commutative square of vector bundles as above but where the bottom arrow is a morphism of vector bundles above U' pulled back to U via $u \times \text{id}_X$. Since the pullback functor $(u \times \text{id}_X)^* : \text{Vect}(U' \times X) \longrightarrow \text{Vect}(U \times X)$ preserves tensor products, \otimes_1 is given by:

$$\begin{aligned} &\left(\begin{array}{ccc} E & \xrightarrow{f} & F \\ a \downarrow & & \downarrow b \\ (u \times \text{id}_X)^* E' & \xrightarrow{(u \times \text{id}_X)^* f'} & (u \times \text{id}_X)^* F' \end{array}, \begin{array}{ccc} V & \xrightarrow{g} & W \\ c \downarrow & & \downarrow d \\ (u \times \text{id}_X)^* V' & \xrightarrow{(u \times \text{id}_X)^* g'} & (u \times \text{id}_X)^* W' \end{array} \right) \\ &\longmapsto \begin{array}{ccc} E \otimes V & \xrightarrow{f \otimes g} & F \otimes W \\ (u \times \text{id}_X)^* (a \otimes c) \downarrow & & \downarrow (u \times \text{id}_X)^* (b \otimes d) \\ (u \times \text{id}_X)^* (E' \otimes V') & \xrightarrow{(u \times \text{id}_X)^* (f' \otimes g')} & (u \times \text{id}_X)^* (F' \otimes W') \end{array} \end{aligned}$$

□

We are now ready to define, or perhaps redefine in our language, the moduli stacks of Higgs bundles.

Definition 6.3 (Moduli Stack of Higgs Bundles). We consider again the simplicial set P shown in 6 and define the following maps:

- (i) We will write \mathcal{M}_P for $\mathcal{M}_{\text{Vect}(X),P}$ and \mathcal{M}_k for $\mathcal{M}_{\text{Vect}(X),\Delta^k}$, for brevity.
- (ii) $\widehat{\text{id}}_K : \text{pt} \rightarrow \mathcal{M}_1$ corresponding to the map $\text{id}_K : K \rightarrow K$
- (iii) $\widehat{\wedge} : \text{pt} \rightarrow \mathcal{M}_1$ corresponding to the map $\wedge : K \otimes K \rightarrow K \wedge K$
- (iv) $z : \text{pt} \rightarrow \mathcal{M}_0$ corresponding to the zero vector bundle 0 over X .
- (v) For a simplex $s : \Delta_k \rightarrow P$, we will write \mathcal{M}_s for a copy of $\mathcal{M}_{\text{Vect}(X),\Delta^k}$. We will write π_s for the map $\mathcal{M}_{\text{Vect}(X),s} : \mathcal{M}_P \rightarrow \mathcal{M}_s$ of Definition 4.4. For instance, $\pi_{e_{ab}}$ is the map that sends a quiver bundle of shape P to the edge indexed by e_{ab} .

With these, we first define a map:

$$\begin{array}{c}
 \mathcal{M}_P \\
 \downarrow (\pi_{e_{ab}}, \pi_a) \\
 \mathcal{M}_{e_{ab}} \times \mathcal{M}_a \\
 \downarrow \text{id} \times e \\
 \mathcal{M}_{e_{ab}} \times \mathcal{M}_1 \\
 \downarrow \simeq \\
 \mathcal{M}_{e_{ab}} \times \text{pt} \times \mathcal{M}_1 \times \text{pt} \times \text{pt} \\
 \downarrow \text{id} \times \widehat{\text{id}}_K \times \text{id} \times \widehat{\wedge} \times z \\
 \mathcal{M}_{e_{ab}} \times \mathcal{M}_1 \times \mathcal{M}_1 \times \mathcal{M}_1 \times \mathcal{M}_{b'} \\
 \downarrow \otimes_1 \times \otimes_1 \times \text{id} \\
 \mathcal{M}_{e_{bc}} \times \mathcal{M}_{e_{cd}} \times \mathcal{M}_{b'}
 \end{array}$$

and call it η . We then define the moduli stack of K -twisted Higgs bundles on X to be the following equalizer of stacks (recall that all limits are taken within the respective quasicategories and so in this case, this is a $(2, 1)$ -limit):

$$\begin{array}{ccc}
 \mathcal{M}_{\text{Higgs}(X,K)} & \longrightarrow & \mathcal{M}_P \\
 & & \eta \downarrow \downarrow (\pi_{e_{bc}}, \pi_{e_{cd}}, \pi_{b'}) \\
 & & \mathcal{M}_{e_{bc}} \times \mathcal{M}_{e_{cd}} \times \mathcal{M}_{b'}
 \end{array}$$

Remark 6.4. Using Lemma 6.1 and Guess 6.2, we see that the map η in the above construction implements the following idea:

- (i) Take a diagram of vector bundles over $U \times X$ of shape P .
- (ii) Take the edge indexed by e_{ab} and tensor it with the identity of pr_2^*K
- (iii) Take the vertex indexed by a , take its identity morphism and tensor that with

$$pr_2^*\wedge : pr_2^*(K \otimes K) \simeq pr_2^*K \otimes pr_2^*K \longrightarrow pr_2^*(K \wedge K) \simeq pr_2^*K \wedge pr_2^*K$$

The equalizer $\mathcal{M}_{\text{Higgs}(X,K)}$ is then the substack of \mathcal{M}_P whose U -points are diagrams of shape P such that the morphism indexed by e_{bc} is the morphism indexed by e_{ab} tensored with $\text{id}_{pr_2^*K}$, and the morphism indexed by e_{cd} is the identity of the vertex indexed by a tensored with $pr_2^*\wedge$, and in addition, the vertex indexed by b' is the zero vector bundle.

By this remark, we have:

Theorem 6.5. *A U -point of $\mathcal{M}_{\text{Higgs}(X,K)}$ corresponds to a commutative diagram of the form:*

$$\begin{array}{ccc} E & \xrightarrow{\phi} & E \otimes pr_2^*K \\ \downarrow & & \downarrow \phi \otimes \text{id}_{pr_2^*K} \\ & & E \otimes pr_2^*K \otimes pr_2^*K \\ & & \downarrow \text{id}_E \otimes pr_2^*\wedge \\ 0 & \longrightarrow & E \otimes pr_2^*K \wedge pr_2^*K \end{array}$$

Remark 6.6. One point to note is that in the infinity categorical setting, this construction will lead to diagrams that commute up to “homotopy” with respect to the appropriate notion of homotopy in the given infinity categorical setting, and in this case we do not just get a Higgs bundle but a Higgs bundle along with a specific witness for its integrability.

Remark 6.7. If we restrict attention to a curve X over \mathbb{C} , then the commutativity of the diagram in the above theorem is automatic as $pr_2^*K \wedge pr_2^*K \simeq pr_2^*(K^{\wedge 2}) \simeq pr_2^*(0) = 0$. Hence, in this case, we recover the construction of [CW17, §7.4].

Up to now, we have a reconstruction of the moduli stack of Higgs bundles, but this perspective leads to the construction of a different moduli stack that, to the best of our knowledge, has not yet appeared in the literature — a moduli stack whose points are morphisms of Higgs bundles.

Definition 6.8 (Moduli Stack of Higgs Bundle Morphisms). Let us draw $S := \Delta^1 \times \Delta^1$ as:

$$\begin{array}{ccc} a & \xrightarrow{u} & b \\ v \downarrow & & \downarrow w \\ c & \xrightarrow{y} & d \end{array}$$

Consider the moduli stack $\mathcal{M}_{\text{Vect}(X),S}$ which we write as \mathcal{M}_S . Using notation similar to the Definition 6.3, we consider the map:

$$\xi : \mathcal{M}_S \xrightarrow{\pi_v} \mathcal{M}_1 \xrightarrow{\simeq} \mathcal{M}_1 \times \text{pt} \xrightarrow{\text{id} \times \widehat{\text{id}}_K} \mathcal{M}_1 \times \mathcal{M}_1 \xrightarrow{\otimes_1} \mathcal{M}_1$$

We define the moduli of stack of morphisms of K -twisted pre-Higgs bundles as the following equalizer of stacks:

$$\mathcal{M}_{\text{preHiggs}(X,K),1} \longrightarrow \mathcal{M}_S \xrightleftharpoons[\pi_w]{\xi} \mathcal{M}_1$$

Using Lemma 6.1, we can see that the U -points of $\mathcal{M}_{\text{preHiggs}(X,K),1}$ are precisely diagrams of vector bundles of the form:

$$(7) \quad \begin{array}{ccc} E & \xrightarrow{\phi} & E \otimes pr_2^* K \\ f \downarrow & & \downarrow f \otimes \text{id} \\ F & \xrightarrow{\psi} & F \otimes pr_2^* K \end{array}$$

We write:

$$\pi'_q : \mathcal{M}_{\text{preHiggs}(X,K),1} \longrightarrow \mathcal{M}_S \xrightarrow{\pi_q} \mathcal{M}_{\Delta^1}$$

for $q = u : \Delta^1 \longrightarrow S$ or $q = y : \Delta^1 \longrightarrow S$ and

$$\pi'_{e_{ab}} : \mathcal{M}_{\text{Higgs}(X,K)} \longrightarrow \mathcal{M}_P \xrightarrow{\pi_{e_{ab}}} \mathcal{M}_1$$

We then define the moduli stack of morphisms of K -twisted Higgs bundles to be the cone point of the following limit diagram:

$$\begin{array}{ccccc} & & \mathcal{M}_{\text{Higgs}(X,K),1} & & \\ & \swarrow s & \downarrow & \searrow t & \\ \mathcal{M}_{\text{Higgs}(X,K)} & & \mathcal{M}_{\text{preHiggs}(X,K),1} & & \mathcal{M}_{\text{Higgs}(X,K)} \\ & \searrow \pi'_{e_{ab}} & \swarrow \pi'_u & \searrow \pi'_y & \swarrow \pi'_{e_{ab}} \\ & & \mathcal{M}_1 & & \mathcal{M}_1 \end{array}$$

We call the canonical maps s and t to $\mathcal{M}_{\text{Higgs}(X,K)}$ the source and target maps.

Using arguments similar to the ones we used to examine U -points of the other stacks constructed so far — for instance, Definition 6.3 — we have the following result:

Theorem 6.9. *A U -point of $\mathcal{M}_{\text{Higgs}(X,K),1}$ is a diagram formed by gluing the following diagrams along the ϕ and ψ edges:*

$$\begin{array}{ccc}
 E & \xrightarrow{\phi} & E \otimes pr_2^* K \\
 \downarrow & & \downarrow \phi \otimes \text{id}_{pr_2^* K} \\
 & & E \otimes pr_2^* K \otimes pr_2^* K \\
 & & \downarrow \text{id}_E \otimes pr_2^* \wedge \\
 0 & \longrightarrow & E \otimes pr_2^* K \wedge pr_2^* K
 \end{array}
 \qquad
 \begin{array}{ccc}
 F & \xrightarrow{\psi} & F \otimes pr_2^* K \\
 \downarrow & & \downarrow \psi \otimes \text{id}_{pr_2^* K} \\
 & & F \otimes pr_2^* K \otimes pr_2^* K \\
 & & \downarrow \text{id}_F \otimes pr_2^* \wedge \\
 0 & \longrightarrow & F \otimes pr_2^* K \wedge pr_2^* K
 \end{array}$$

$$\begin{array}{ccc}
 E & \xrightarrow{\phi} & E \otimes pr_2^* K \\
 f \downarrow & & \downarrow f \otimes \text{id} \\
 F & \xrightarrow{\psi} & F \otimes pr_2^* K
 \end{array}$$

The map s sends such a U -point to the top-left diagram and t sends it to the top-right diagram.

We end this section by stating an easy corollary of our work so far and a guess.

Corollary 6.10. *If X satisfies the hypotheses of Theorem 4.10 and Guess 6.2 holds, the stacks $\mathcal{M}_{\text{Higgs}(X,K)}$ and $\mathcal{M}_{\text{Higgs}(X,K),1}$ are Artin, locally of finite presentation, quasi-separated and has affine stabilizers. If X and $\mathcal{M}_{\text{Vect}(X)}$ have affine diagonal, then so do $\mathcal{M}_{\text{Higgs}(X,K)}$ and $\mathcal{M}_{\text{Higgs}(X,K),1}$.*

Proof. It suffices to see that they are constructed as iterated pullbacks of stacks satisfying these properties. \square

Remark 6.11. This result also has a derived counterpart. [PS20, Lemma 5.3.1] combined with [PS23, Corollary 4.6] yield algebraicity and local finite presentation of the derived moduli stacks of Higgs bundle diagrams over a very general base stack. The algebraicity and local finite presentation of the non-derived stacks can be recovered from this. However, our methods of construction and proof are completely in the non-derived setting and yield some more properties of the constructed moduli stacks.

Guess 6.12. *If Guess 6.2 holds, then there exist maps*

$$e : \mathcal{M}_{\text{Higgs}(X,K)} \longrightarrow \mathcal{M}_{\text{Higgs}(X,K),1}$$

and

$$c : \mathcal{M}_{\text{Higgs}(X,K),1} \times_{\mathcal{M}_{\text{Higgs}(X,K)}} \mathcal{M}_{\text{Higgs}(X,K),1} \longrightarrow \mathcal{M}_{\text{Higgs}(X,K),1}$$

such that $(\mathcal{M}_{\text{Higgs}(X,K)}, \mathcal{M}_{\text{Higgs}(X,K),1}, s, t, e, c)$ is an internal category in $\text{St}_{\text{CRing}^\heartsuit, \text{op}}^1$.

Proof sketch. We need only provide the maps e and c , while the rest needs to be verified by chasing U -points. The map e is given by the diagram of the form 7 while the composition map is given by pasting such diagrams and taking the composition of the composable arrows. \square

6.2. Non-Abelian Hodge Theory. In line with the categorification of the moduli problem for Higgs bundles, it is natural to consider the categorified versions of the Hitchin morphism and the non-Abelian Hodge correspondence. The questions that need to be answered in order to make these ideas precise are as follows:

- (1) Denoting the Hitchin base as H , we can then ask: is there a stack H_1 and maps $s, t : H_1 \rightarrow H$, $e : H \rightarrow H_1$ and $c : H_1 \times_H H_1 \rightarrow H_1$ that form an internal category in stacks? See the Conventions subsection in Section 1 for the interpretations of s, t, e, c and [Ghi19] for detailed discussion of internal category theory.
- (2) The Hitchin morphism $\text{Hitchin} : \mathcal{M}_{\text{Higgs}(X, K)} \rightarrow H$ is given by viewing a Higgs field $\phi : E \rightarrow E \otimes K$ as a global section of $E^\vee \otimes E \otimes K$ and taking the maps $c_i : E^\vee \otimes E \otimes K \rightarrow K^{\otimes i}$ given by the i -th characteristic coefficient maps. We can then ask: is there a morphism

$$\text{Hitchin}_1 : \mathcal{M}_{\text{Higgs}(X, K), 1} \rightarrow H_1$$

that together with the usual Hitchin morphism, form an internal functor of category stacks? That is, are there commutative diagrams of the form:

$$\begin{array}{ccc} \mathcal{M}_{\text{Higgs}(X, K), 1} & \xrightarrow{\text{Hitchin}_1} & H_1 \\ \begin{array}{c} \downarrow \downarrow \downarrow \\ s \quad t \quad e \\ \downarrow \downarrow \downarrow \end{array} & & \begin{array}{c} \downarrow \downarrow \downarrow \\ s \quad t \quad e \\ \downarrow \downarrow \downarrow \end{array} \\ \mathcal{M}_{\text{Higgs}(X, K)} & \xrightarrow{\text{Hitchin}} & H \end{array}$$

$$\begin{array}{ccc} \mathcal{M}_{\text{Higgs}(X, K), 1} \times \mathcal{M}_{\text{Higgs}(X, K)} & \xrightarrow{\text{Hitchin}_1 \times \mathcal{M}_{\text{Higgs}(X, K)}} & \mathcal{M}_{\text{Higgs}(X, K), 1} \xrightarrow{\text{Hitchin}_1} H_1 \times_H H_1 \\ \downarrow c & & \downarrow c \\ \mathcal{M}_{\text{Higgs}(X, K), 1} & \xrightarrow{\text{Hitchin}_1} & H_1 \end{array}$$

- (3) What is the category stack that parametrizes representations of the fundamental group? That is, are there moduli stacks $\mathcal{M}_{\text{Rep}(\pi_1(X))}$ and $\mathcal{M}_{\text{Rep}(\pi_1(X)), 1}$ such that the points of the first correspond to representations of some sort of fundamental group of X and those of the second correspond to morphisms of such representations in any reasonable sense? Do they form a category stack? Does it admit a

functor of internal categories to the categorified Hitchin base as we have asked for Higgs bundles? There is a potential answer to the first few questions: for any stack X , we can take its Betti “shape” X_{Betti} — described in, for example, [Por17; PS20] but originating in works of Carlos Simpson — and consider $\mathcal{M}_{\text{Vect}(X_{\text{Betti}}), \Delta^n}$ for $n = 0, 1, \dots$. For $n = 0$, the points of this stack are representations of $\pi_1(X)$, when X is a smooth complex projective curve, say. So, it is natural to expect that points of the morphism stack, that is $\mathcal{M}_{\text{Vect}(X_{\text{Betti}}), 1} = \mathcal{M}_{\text{Vect}(X_{\text{Betti}}), \Delta^1}$, will correspond to morphisms of $\pi_1(X)$ –representations.

- (4) Similarly, what is the right definition of a category stack parametrizing flat connections and their morphisms? Again, there is an answer in terms of shapes: take $\mathcal{M}_{\text{Vect}(X_{\text{dR}}), \Delta^n}$ for $n = 0, 1, \dots$, where X_{dR} is the de Rham shape of X , described in [Por17; PS20].
- (5) Can the equivalences of moduli spaces taking part in the Riemann-Hilbert correspondence and the non-Abelian Hodge correspondence be extended to equivalences of the respective internal category stacks being asked for in the previous questions? There is a pressing issue to be addressed here: there is no known morphism of stacks extending the homeomorphism of moduli spaces realizing the non-Abelian Hodge correspondence. Hence, on the nose, this cannot be done — even at the object level, there is no known map.

However, we can consider the following strategy. There is a dg–equivalence of categories between Higgs bundles and flat connections, for a suitably chosen base. One can try to assemble the mapping of morphisms taking part in this equivalence into a mapping of stacks:

$$\mathcal{M}_{\text{Higgs}(X, K), 1} \longleftrightarrow \mathcal{M}_{\text{Vect}(X_{\text{dR}}), 1}$$

Then, one can take the composite:

$$\mathcal{M}_{\text{Higgs}(X, K)} \xrightarrow{e} \mathcal{M}_{\text{Higgs}(X, K), 1} \longrightarrow \mathcal{M}_{\text{Vect}(X_{\text{dR}}), 1} \longrightarrow \mathcal{M}_{\text{Vect}(X_{\text{dR}})}$$

where the first map sends an object to its identity arrow and the last map sends an arrow to its source or target. This will be one possible mapping of stacks but it is most likely not the non-Abelian Hodge map away from the stable locus. However, one can then consider properties of this map to measure how badly the non-Abelian Hodge map fails away from the stable locus.

We can ask even more questions analogous to questions explored in the usual study of Higgs bundles. For instance, If the answer to (2) above is yes, what do the fibres of Hitchin_1 look like? Whatever the fibres are, for each fibre, we can consider the image of the fibre under the source and target maps $\mathcal{M}_{\text{Higgs}(X, K), 1} \longrightarrow \mathcal{M}_{\text{Higgs}(X, K)}$. That is, for each fibre Y of Hitchin_1 we get two fibres Y_0, Y_1 of Hitchin and pair of maps:

$$Y_0 \xleftarrow{s} Y \xrightarrow{t} Y_1$$

We can then ask what kind of information Y might contain about the Y_0 and Y_1 and if Y somehow relates these two fibres. We can go further and ask what the analogue of the \mathbb{C}^* -action is in this setting and so on.

Finally, we note that what we have discussed in this paper is just one level of categorification. That is we have only discussed internal categories in stacks such that its object of objects parametrizes vector bundles, Higgs bundles, quiver bundles, etc. and its object of morphisms parametrizes morphisms of these objects. We can ask for simplicial stacks whose n -th level parametrizes n -simplices in the quasicategories of vector bundles, quiver bundles, Higgs bundles in the derived algebraic, spectral algebraic and derived analytic settings. Then, we can ask for a non-Abelian Hodge theory in this more complete setting. The considerations discussed in this subsection will form a major portion of the first named author's upcoming thesis.

7. MODULI THEORY AND HOMOTOPY THEORY

We conclude by discussing some possible links of the perspectives of this paper with homotopy theory.

7.1. General Moduli Theory. Thinking of 1-stacks as categories fibred in groupoids over the 1-category of affine schemes, there is a more intuitive definition of stacks of quiver bundles. Consider a 1-category I and consider quiver bundles of shape I over X . Now, take the prestack $pr_2 : I \times \mathcal{C} \rightarrow \mathcal{C}$, where the product is just the product of categories. We can then take the mapping prestack $\text{Map}(I \times \mathcal{C}, \mathcal{M}_{\text{Vect}(X)})$ whose U -points are maps $U \times I \times \mathcal{C} \rightarrow \mathcal{M}_{\text{Vect}(X)}$ which are, in turn, equivalent to maps $U \times I \times \mathcal{C} \times X \rightarrow \text{Vect}$. However, these are again equivalent to maps $I \times \mathcal{C} \rightarrow \text{Vect}(U \times X)$, which commute with the projections to \mathcal{C} . Such a map is just a diagram of vector bundles over $U \times X$. We note that the mapping prestack is, in fact, a stack since $\mathcal{M}_{\text{Vect}(X)}$ is. Hence, this serves as an alternate definition of a moduli stack of quiver bundles over X . If we considered 1-stacks as just sheaves on \mathcal{C} , then this would be equivalent to the mapping stack $\text{Map}(\underline{I}, \mathcal{M}_{\text{Vect}(X)})$, where \underline{I} is the constant sheaf valued at I . With this, we would like to make a conjecture:

Definition 7.1. Let $X \in \text{St}_{\mathcal{C}}$ be a stack over \mathcal{C} . We define

$$\begin{aligned} \mathcal{M}_{\text{Vect}(X), I}^{\text{cat}} &:= \text{Map}(\underline{I}, \mathcal{M}_{\text{Vect}(X)}) \\ &\simeq \text{Map}(\underline{I}, \text{Map}(X, \text{Vect})) \\ &\simeq \text{Map}(X \times \underline{I}, \text{Vect}) \end{aligned}$$

to be the category theoretic moduli stack of quiver bundles over X .

Conjecture 7.2. *There is an equivalence of stacks $\mathcal{M}_{\text{Vect}(X), I}^{\text{cat}} \simeq \mathcal{M}_{\text{Vect}(X), I}$ for all I . In fact, this equivalence is a natural equivalence of functors $\text{sSet} \rightarrow \text{St}_{\text{CRing}^{\heartsuit, \text{op}}}^1$.*

Remark 7.3. For another definition of the above concept, we could consider the functor category $\mathrm{Fun}(I, \mathrm{unstr}(\mathcal{M}_{\mathrm{Vect}(X)}))$ but we need a Cartesian fibration from it to \mathcal{C} in order to consider it as even a prestack. We could take the map

$$\mathrm{Fun}(I, \mathrm{unstr}(\mathcal{M}_{\mathrm{Vect}(X)})) \longrightarrow \mathrm{Fun}(I, \mathcal{C}) \longrightarrow \mathcal{C}$$

where the first map is given by post-composition by the Cartesian fibration $\mathrm{unstr}(\mathcal{M}_{\mathrm{Vect}(X)}) \longrightarrow \mathcal{C}$ and the second map is taking either a colimit or a limit. However, one needs to show that this will give a Cartesian fibration and will straighten to a sheaf, and then show an appropriate algebraicity in the concrete examples we have in mind. We can then try to show an equivalence with the above definition.

While we did not pursue this perspective in this paper, it is worth noting that this is a more general approach as it does not require the universal vector bundle \mathcal{E}_X . Recall that the most crucial object in our constructions was the vector bundle $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$. That is, for a general moduli problem $\mathcal{M} : \mathcal{C}^{\mathrm{op}} \longrightarrow \mathcal{S}$ where there is no analogue of $\mathcal{E}_X^\vee \boxtimes \mathcal{E}_X$, we can still define moduli stacks \mathcal{M}_I whose points are I -shaped diagrams of objects parametrized by the original moduli problem as simply the mapping prestack $\mathrm{Map}(I, \mathcal{M})$, which will, at the very least, be a stack as long as \mathcal{M} is. An interesting example of this would be the moduli problem for elliptic curves. With this setup, one may examine the conditions on \mathcal{M} needed to make \mathcal{M}_I algebraic or have other desirable properties. We intend to pursue this more general approach for a wide range of moduli problems in future work.

7.2. Speculations around Homotopy Theory. We end this section by discussing, in imprecise terms, some potential links between moduli theory and homotopy theory facilitated by the perspectives of this paper. Homotopy theory, in the most elementary sense, is concerned with studying mapping spaces between topological spaces. That is, the sets of maps between topological spaces are not just discrete sets and come equipped with their own topology. Said differently, if we restrict attention to nice enough — that is, compactly generated weakly Hausdorff (CGWH) topological spaces — then the category of such spaces admit an enrichment in Kan complexes, which gives a homotopy theory that is equivalent to the homotopy theory of simplicial sets. There are two ways of saying this more precisely:

- (1) The category of CGWH spaces admits a model structure Quillen equivalent to the Kan-Quillen model structure of simplicial sets.
- (2) The simplicial or coherent nerve of the simplicial category of CGWH spaces is equivalent as a quasicategory to the quasicategory of Kan complexes.

Now, given a classical moduli problem valued in groupoids $\mathcal{M} : \mathcal{C}^{\mathrm{op}} \longrightarrow \mathrm{Grpd}$, we can take the moduli stacks \mathcal{M}_{Δ^n} for $n = 0, 1, 2, \dots$, as defined in

the previous subsection along with the natural maps

$$\mathcal{M}_f : \mathcal{M}_{\Delta^n} = \text{Map}(\Delta^n, \mathcal{M}) \longrightarrow \text{Map}(\Delta^m, \mathcal{M}) = \mathcal{M}_{\Delta^m}$$

induced by maps $f : \Delta^m \longrightarrow \Delta^n$. This data assembles into a simplicial object $\mathcal{M}_\bullet = \mathcal{M}_{\Delta^\bullet} : \Delta^{\text{op}} \longrightarrow \text{St}_{\mathbb{C}}^1$.

On the other hand, for any two objects of \mathcal{M} given by maps $a : U \longrightarrow \mathcal{M}$ and $b : V \longrightarrow \mathcal{M}$, inspired by [Lur09, §1.2.2], we can define a simplicial stack $\mathcal{M}^R(a, b)_\bullet$ whose n -th degree is defined by the pullback:

$$\begin{array}{ccc} \mathcal{M}^R(a, b)_n & \longrightarrow & \mathcal{M}_{\Delta^{n+1}} \\ \downarrow & \lrcorner & \downarrow (d_0, \dots, d_{n+1}) \\ U \times V & \xrightarrow{(a, \dots, a, b)} & \mathcal{M}^{n+1} \times \mathcal{M} \end{array}$$

where the d_i are the face maps corresponding to vertex inclusions $\Delta^0 \longrightarrow \Delta^n$. Roughly speaking, $\mathcal{M}^R(a, b)_0$ is to be thought of as the stack parametrizing maps $a \longrightarrow b$; $\mathcal{M}^R(a, b)_1$, as the stack parametrizing homotopies $H : g \Longrightarrow h$ of maps $g, h : a \longrightarrow b$; $\mathcal{M}^R(a, b)_2$, as the stack parametrizing three homotopies $H_{gh} : g \Longrightarrow h, H_{hr} : h \Longrightarrow r$ and $H_{gr} : g \Longrightarrow r$, and a higher homotopy between $H_{hr} \circ H_{gh}$ and H_{gr} ; and, so on. Changing (a, \dots, a, b) to (a, b, \dots, b) above, we define a simplicial stack $\mathcal{M}^L(a, b)_\bullet$. One can then try defining something akin to an enriched category whose objects form not a set but a stack \mathcal{M} and for any two objects $a, b \in \mathcal{M}$, the simplicial stack of “maps” $a \longrightarrow b$ is $\text{Map}^R(a, b)_\bullet$ or $\text{Map}^L(a, b)_\bullet$. Let us denote this object, if it exists, as \mathcal{M}^Δ . The constructions \mathcal{M}_\bullet and \mathcal{M}^Δ can be viewed as using the data of a classical moduli problem to produce an infinity categorical moduli problem that is different from taking its derived or spectral version.

These constructions are reminiscent of the theory of simplicial sets and we can ask if any of the aspects of the homotopy theory of simplicial sets or the theory of quasicategories can be translated to this setting, and, if they can be related to available homotopy theories in algebraic geometry such as [MV99] or the more recent [AI23].

A few questions that one might ask in this direction are:

- (1) Taking $\mathcal{M} = \mathcal{M}_{\text{Vect}(X)}$ and two objects $a, b \in \mathcal{M}_{\text{Vect}(X)}(U)$ corresponding to two vector bundles E_a, E_b over $U \times X$, how do the mapping stacks $\mathcal{M}^R(a, b)$ compare to the Hom stack $\mathcal{H}\text{om}(E_a, E_b)$ seen as an object in the quasicategory of motivic spaces of [MV99] or that of motivic spectra in [AI23]? It is likely that in the Morel-Voevodsky quasicategory, these mapping stacks will be contractible but not so in the quasicategory of non- \mathbb{A}^1 -invariant motivic spectra.
- (2) Taking $\mathcal{M} = \mathcal{M}_{\text{Vect}(X)}$ again, we can consider the simplicial object $\mathcal{M}_\bullet : \Delta^{\text{op}} \longrightarrow \text{St}_{\mathbb{C}}^1$ composed with the inclusion $\text{St}_{\mathbb{C}}^1 \hookrightarrow \text{St}_{\mathbb{C}}$ followed

by one of the localization functors of Morel-Voevodsky or Annala-Iwasa. In this situation, we have a simplicial motivic space or a simplicial motivic spectrum and we can ask: how do the maps relate the homotopical properties of the individual levels of the simplicial object with one another?

- (3) We can ask the same questions taking \mathcal{M} to be some moduli stack of elliptic curves or of Higgs bundles, and so on.
